The quantity  $J$  is given in this table in units of 0<sup>s</sup>.00001, and is to be multiplied by  $\tan^2\delta_0$  to give the second-order correction in the calculation of the apparent right ascension of a star.

The complete formula is :

$$\alpha = \alpha_0 + \tau\mu_\alpha + Aa + Bb + Cc + Dd + E + J \tan^2\delta_0$$

The quantity  $J'$  is given in this table in units of 0<sup>''</sup>.0001, and is to be multiplied by  $\tan \delta_0$  to give the second-order correction in the calculation of the apparent declination of a star.

The complete formula is :

$$\delta = \delta_0 + \tau\mu_0 + Aa' + Bb' + Cc' + Dd' + J' \tan \delta_0$$

The quantity  $J$  is given in this table in units of 0<sup>s</sup>.00001, and is to be multiplied by  $\tan^2 \delta_0$  to give the second-order correction in the calculation of the apparent right ascension of a star.

The complete formula is :

$$\alpha = \alpha_0 + \tau \mu_\alpha + Aa + Bb + Cc + Dd + E + J \tan^2 \delta_0$$

The quantity  $J'$  is given in this table in units of 0<sup>''</sup>.0001, and is to be multiplied by  $\tan \delta_0$  to give the second-order correction in the calculation of the apparent declination of a star.

The complete formula is :

$$\delta = \delta_0 + \tau\mu_\delta + Aa' + Bb' + Cc' + Dd' + J' \tan \delta_0$$

There are four eclipses, two of the Sun and two of the Moon.

|     |            |                            |
|-----|------------|----------------------------|
| I   | April 24   | Total eclipse of the Moon  |
| II  | May 9      | Partial eclipse of the Sun |
| III | October 18 | Total eclipse of the Moon  |
| IV  | November 2 | Total eclipse of the Sun   |

A correction of  $-0^{\circ}.6$  has been applied to the tabular latitude of the Moon. This correction is given below in the form of corrections to the right ascension and declination of the Moon.

|          | d  | $\Delta\alpha$<br>s | $\Delta\delta$<br>" |
|----------|----|---------------------|---------------------|
| April    | 24 | - 0.014             | - 0.56              |
| May      | 9  | + 0.012             | - 0.58              |
| October  | 18 | + 0.015             | - 0.56              |
| November | 2  | - 0.013             | - 0.57              |

The arguments are given in Ephemeris Time. The hour angle  $\mu$  and the longitudes are referred to the ephemeris meridian. East longitudes are negative. Once the value of  $\Delta T$  is known, the data on these pages may be expressed in terms of Universal Time in the following manner:

Convert all arguments into Universal Time by the relation  $U.T. = E.T. - \Delta T$ .

Apply the correction  $-1.0027 \Delta T$  to  $\mu$  and to the longitudes, in order to refer them to the meridian of Greenwich, remembering that a second of time is equivalent to 15 seconds of arc.

Leave all other quantities unchanged.

I.—*Total Eclipse of the Moon*, April 24; the beginning of the penumbral phase visible in North America except the northeast part, the western part of South America, the Pacific Ocean, the east coast of Asia, Australia, New Zealand, and Antarctica; the end visible in the Pacific Ocean except the southeastern part, the eastern part of Asia, the eastern part of the Indian Ocean, Indonesia, Australia, New Zealand, and Antarctica.

The closest approach of the Earth to the axis of shadow is approximately 14 miles, and occurs at the time and place of greatest eclipse. Total phases of this eclipse will occur at all places within the small area noted "Path of Total Eclipse." limited on one side by the curve "Maximum Eclipse at Sunrise."

This map illustrates the path of an eclipse across North America and the Atlantic Ocean. The map is centered on the North Pole, showing the Arctic region and the surrounding continents of Asia, Europe, and North America. The Atlantic Ocean is visible to the east of North America. The map includes a grid of latitude and longitude lines. The eclipse path is marked by a solid line, with dashed lines indicating the limits of the eclipse. Key locations along the path are labeled, including 'Sunrise at', 'Eclipse begins at', 'Maximum Eclipse at', 'Eclipse ends at', and 'Sunset'. The map also shows the 'Greatest Eclipse' path. A legend in the bottom right corner identifies the symbols used: a dashed line for 'Semiduration', a solid line for 'Middle of Eclipse', and a dotted line for 'Ephemeris Time is used'. The map includes a scale bar at the bottom left, indicating distances in miles (0 to 1000) and kilometers (0 to 1600).

Apparent distance of satellite is  $F\frac{a}{\Delta}$

Position angle of satellite is  $p_1+p_2$

Jupiter is in opposition January 20, but at this date the Earth is very near the planes of the orbits of the satellites, and hence the apparent orbits approximate straight lines.

I. Oct. 17

 $x_1 = -1.9, y_1 = 0.0$ 

II. Oct. 15

 $x_1 = -2.4, y_1 = -0.1$ 

III. Oct. 17

 $x_1 = -3.2, y_1 = -0.1$   
 $x_2 = -1.3, y_2 = -0.1$ 

IV. Oct. 18

 $x_1 = -5.0, y_1 = -0.1$   
 $x_2 = -3.0, y_2 = -0.1$ 

NOTE.—I. denotes ingress; E., egress; D., disappearance; R., reappearance; Ec., eclipse; Oc., occultation; Tr., transit of the satellite; Sh., transit of the shadow.

Factor by which axes of outer edge of outer ring are to be multiplied to obtain axes of:  
 Inner edge of outer ring 0.8801      Inner edge of inner ring 0.6650  
 Outer edge of inner ring 0.8599      Inner edge of dusky ring 0.5486

If the horizontal parallax,  $\pi = 8''.80/\text{distance}$ , is known the parallax corrections are:

$$\Delta\alpha = \frac{\pi}{\sin \delta} \times \rho \cos \phi' \sin h \sec \delta \quad \Delta\delta = \pi \times \rho \cos \phi' (\tan \phi' \cos \delta - \cos h \sin \delta)$$

where  $h = \theta - \alpha$  and  $\theta = \text{sidereal time at } 0^h + \text{sidereal equivalent of U.T.} - \lambda$

Otherwise add  $\Delta X = \Delta_{\alpha} \cos \theta$ ,  $\Delta Y = \Delta_{\alpha} \sin \theta$ ,  $\Delta Z$  to solar coordinates to eliminate parallax.

If the horizontal parallax,  $\pi=8''.80/\text{distance}$ , is known the parallax corrections are:

$$\Delta\alpha = \pi \times \rho \cos \phi' \sin h \sec \delta \quad \Delta\delta = \pi \times \rho \cos \phi' (\tan \phi' \cos \delta - \cos h \sin \delta)$$

where  $h = \theta - \alpha$  and  $\theta = \text{sidereal time at } 0^h + \text{sidereal equivalent of U.T.} - \lambda$

Otherwise add  $\Delta X = \Delta x, \cos \theta, \Delta Y = \Delta y, \sin \theta, \Delta Z$  to solar coordinates to eliminate parallax.

If the horizontal parallax,  $\pi=8''.80$ /distance, is known the parallax corrections are:

$$\Delta\alpha = \pi \times \rho \cos \phi' \sin h \sec \delta \quad \Delta\delta = \pi \times \rho \cos \phi' (\tan \phi' \cos \delta - \cos h \sin \delta)$$

where  $h = \theta - \alpha$  and  $\theta$  = sidereal time at 0<sup>h</sup> + sidereal equivalent of U.T. -  $\lambda$

Otherwise add  $\Delta X = \Delta\alpha \cos \theta$ ,  $\Delta Y = \Delta\alpha \sin \theta$ ,  $\Delta Z$  to solar coordinates to eliminate parallax.

If the horizontal parallax,  $\pi=8''.80/\text{distance}$ , is known the parallax corrections are:

$$\Delta\alpha=\pi \times \rho \cos \phi' \sin h \sec \delta \quad \Delta\delta=\pi \times \rho \cos \phi' (\tan \phi' \cos \delta - \cos h \sin \delta)$$

where  $h=\theta-\alpha$  and  $\theta$ =sidereal time at 0<sup>h</sup>+sidereal equivalent of U. T.  $-\lambda$

Otherwise add  $\Delta X=\Delta\alpha \cos \theta$ ,  $\Delta Y=\Delta\alpha \sin \theta$ ,  $\Delta Z$  to solar coordinates to eliminate parallax.

If the horizontal parallax,  $\pi=8''.80/\text{distance}$ , is known the parallax corrections are:

$$\Delta\alpha = \pi \times \rho \cos \phi' \sin h \sec \delta \quad \Delta\delta = \pi \times \rho \cos \phi' (\tan \phi' \cos \delta - \cos h \sin \delta)$$

where  $h = \theta - \alpha$  and  $\theta$  = sidereal time at 0<sup>h</sup> + sidereal equivalent of U.T. -  $\lambda$

Otherwise add  $\Delta X = \Delta_{xy} \cos \theta$ ,  $\Delta Y = \Delta_{xy} \sin \theta$ ,  $\Delta Z$  to solar coordinates to eliminate parallax.

If the horizontal parallax,  $\pi=8''.80/\text{distance}$ , is known the parallax corrections are:

$$\Delta\alpha=\pi \times \rho \cos \phi' \sin h \sec \delta \quad \Delta\delta=\pi \times \rho \cos \phi' (\tan \phi' \cos \delta - \cos h \sin \delta)$$

where  $h=\theta-\alpha$  and  $\theta$ =sidereal time at 0<sup>h</sup>+sidereal equivalent of U.T.- $\lambda$

Otherwise add  $\Delta X=\Delta x \cos \theta$ ,  $\Delta Y=\Delta x \sin \theta$ ,  $\Delta Z$  to solar coordinates to eliminate parallax.

If the horizontal parallax,  $\pi = 8''.80/\text{distance}$ , is known the parallax corrections are:

$$\Delta\alpha = \frac{\pi}{\sin h} \times \rho \cos \phi' \sin h \sec \delta \quad \Delta\delta = \pi \times \rho \cos \phi' (\tan \phi' \cos \delta - \cos h \sin \delta)$$

where  $h = \theta - \alpha$  and  $\theta$  = sidereal time at 0<sup>h</sup> + sidereal equivalent of U.T. -  $\lambda$

Otherwise add  $\Delta X = \Delta x \cos \theta$ ,  $\Delta Y = \Delta x \sin \theta$ ,  $\Delta Z$  to solar coordinates to eliminate parallax.

If the horizontal parallax,  $\pi=8''.80/\text{distance}$ , is known the parallax corrections are:

$$\Delta\alpha=\frac{1}{\sin\delta}\pi\times\rho\cos\phi'\sin h\sec\delta \quad \Delta\delta=\pi\times\rho\cos\phi'(\tan\phi'\cos\delta-\cos h\sin\delta)$$

where  $h=\theta-\alpha$  and  $\theta$ =sidereal time at 0<sup>h</sup>+sidereal equivalent of U.T.- $\lambda$

Otherwise add  $\Delta X=\Delta_{\alpha}\cos\theta$   $\Delta Y=\Delta_{\delta}\sin\theta$ ,  $\Delta Z$  to solar coordinates to eliminate parallax.

## INDEX LIST

Actual names of observatories are in bold type.

Names of owners of private observatories are in *italics*.

Radio observatories are designated by R.

## JULIAN DAY NUMBER

DAYS ELAPSED AT GREENWICH NOON OF JANUARY 0

| Julian Calendar |       |               |          |          |          | This table gives the Julian Day numbers for January 0 of every leap year from A. D. 1100 to A. D. 1896, and the reductions to be applied to them to obtain the numbers for January 0 of the leap years in other centuries from 1697 B. C. to A. D. 2296, except in the 20th century which is tabulated on the following two pages. |                    |          |           |           |      |      |  |

| 1               | —     | 215 9357      | 219 5882 | 223 2407 | 226 8932 |  |                    |          |           |           |      |      |  |
|                 |       |               |          |          |          | *For Jan. —1; these century years are not leap years.  |                    |          |           |           |      |      |  |

\*For Jan. —1; these century years are not leap years.

In the following table, for dates from 1582 October 15 to 1583 December 31 inclusive, Gregorian calendar, *diminish all numbers by 10*.

In century years of the Gregorian calendar that are not leap years, for *January 0* use the number 1 instead of the tabular value 0, and for *February 0* use 32 instead of 31.

Latitude of observer is sum of corrected observed altitude of Polaris and (a<sub>0</sub>+a<sub>1</sub>+a<sub>2</sub>).  
Azimuth of Polaris is product of (b<sub>0</sub>+b<sub>1</sub>+b<sub>2</sub>) by secant of latitude.

Latitude of observer is sum of corrected observed altitude of Polaris and (*a*<sub>0</sub>+*a*<sub>1</sub>+*a*<sub>2</sub>).  
Azimuth of Polaris is product of (*b*<sub>0</sub>+*b*<sub>1</sub>+*b*<sub>2</sub>) by secant of latitude.

Latitude of observer is sum of corrected observed altitude of Polaris and (*a*<sub>0</sub>+*a*<sub>1</sub>+*a*<sub>2</sub>).  
Azimuth of Polaris is product of (*b*<sub>0</sub>+*b*<sub>1</sub>+*b*<sub>2</sub>) by secant of latitude.

Latitude of observer is sum of corrected observed altitude of Polaris and ( $a_0+a_1+a_2$ ).  
Azimuth of Polaris is product of ( $b_0+b_1+b_2$ ) by secant of latitude.

$$\alpha_{\text{Date}} = \alpha_{1950} + f + g \sin (G + \alpha_{1950}) \tan \delta_{1950}$$

$$\delta_{\text{Date}} = \delta_{1950} + g \cos (G + \alpha_{1950})$$

In the formula for  $\alpha$ , the last term is to be expressed in seconds of time by multiplying  $g$  in minutes of arc by 4, where the factor 4 is applied by using the tabular value of  $4 \tan \delta$ .

TABLE V  
DIFFERENTIAL ABERRATION

The correction for differential stellar aberration to be added to the observed differences  $\Delta\alpha$  and  $\Delta\delta$  of the right ascension and declination of an object relative to a comparison star, measured in the sense object *minus* star in units of  $1''$  and  $1'$  respectively, to obtain the true differences, is:

In right ascension,  $a\Delta\alpha + b\frac{\Delta\delta}{10}$  in units of  $0.001''$ ,  
In declination,  $c\Delta\alpha + d\frac{\Delta\delta}{10}$  in units of  $0''.01$ ,

where  $a, b, c, d$ , are obtained from the table below with arguments  $H+\alpha$  and  $\delta$ , and may in general be taken out without interpolation; for the signs, see opposite page.

## DIFFERENTIAL ABERRATION

For positive declinations, take the signs of  $b$  and  $c$  (which are always opposite) from the top of the column when the argument  $H+\alpha$  is on the left, from the bottom when  $H+\alpha$  is on the right. For negative declinations, reverse the signs of  $b$  and  $c$ .

The signs of  $a$  and  $d$  (which are always alike) are independent of the sign of  $\delta$ , and also of whether  $H+\alpha$  is on the left or the right.

DIFFERENTIAL PRECESSION AND NUTATION, 1967

The correction for differential precession and nutation to be *added* to the observed differences  $\Delta\alpha$  and  $\Delta\delta$  of the right ascension and declination of an object relative to a comparison star, measured in the sense object *minus* star in units of  $1^m$  and  $1'$  respectively, is:

In right ascension,  $e\Delta\alpha \frac{10 \tan \delta}{15} - f\Delta\delta \frac{10 \sec^2 \delta}{225}$ , units of  $0''.001$ ;  
in declination,  $f\Delta\alpha$ , units of  $0''.01$ ;

where  $e$  and  $f$  are taken from the table below, with the signs given in the table when  $0^\circ \leq \alpha \leq 12^\circ$ , but with the opposite signs when  $12^\circ \leq \alpha \leq 24^\circ$ .

Geocentric Coordinates referred to the International Ellipsoid:

$$\rho \sin \phi' = (S + H) \sin \phi,$$

$$\rho \cos \phi' = (C + H) \cos \phi;$$

H, the altitude above sea-level in units of the equatorial radius of the Earth, is

$$0.1567794 \times 10^{-6} \times \text{altitude in m, or } 0.0477865 \times 10^{-6} \times \text{altitude in ft.}$$

BESSEL'S INTERPOLATION FORMULA

$f_p=f_0+p\delta_{\frac{1}{2}}+B_2(\delta_0^2+\delta_1^2)+B_3\delta_{\frac{3}{2}}^3+B_4(\delta_0^4+\delta_1^4)+\dots$

The maximum truncation error of the interpolate  $f_p$  from neglecting each order of difference is less than 0.5 in the unit of the end figure of the tabular function if

$\delta^2 < 4 \qquad \delta^3 < 60 \qquad \delta^4 < 20 \qquad \delta^5 < 500$

If  $\delta^2$  is replaced by  $\delta_m^2=\delta^2-0.184 \delta^4$ , the corresponding limit for  $\delta^4$  is raised to 1000;  $\delta_{\frac{3}{2}}^3$  may be replaced by  $\delta_{m1}^2-\delta_{m0}^2$ .

PRECEPTS FOR USING THE TABLES

Table XIII. Round the interpolating factor  $p$  to 4 decimals; the required value of  $B_2$  is the tabular value opposite the interval in which  $p$  lies or, if  $p$  exactly equals a tabular argument, the value above and to the right of  $p$ . The effects of third and fourth differences can be estimated from the values of  $B_3$  and  $B_4$  in the last column.

Table XIV. The table is entered with the tabular arguments nearest the true values of  $p$  and  $\delta_0^2+\delta_1^2$ , to obtain directly the value of the second-difference correction; this correction always has the opposite sign to  $\delta_0^2+\delta_1^2$ .

Table XV. The value of  $B_2$  may be obtained by mental linear interpolation since the first difference of  $B_2$  is never greater than 4. The corrections for third and fourth differences, which are usually necessary when Table XIII cannot be used, are taken from the Tables XVI and XVII; these tables are similar to Table XIV, but include a guarding decimal, and require mental interpolation for some ranges of the argument, to reduce the error of the interpolate.

Errors. In addition to the truncation error, an interpolate is subject to errors from the following sources:

|  |  | Maximum error                      |
|--|--|------------------------------------|
| $f_0+p\delta_{\frac{1}{2}}$                                  | Rounding errors in $f_0, f_1$                  | 0.5                                |
| $B_2(\delta_0^2+\delta_1^2)+B_3\delta_{\frac{3}{2}}^3+\dots$ | Rounding errors in tabular values              | 0.2                                |
| $B_2(\delta_0^2+\delta_1^2)$                                 | Rounding error of $B_2$ from Table XIII        | 0.00051( $\delta_0^2-\delta_1^2$ ) |
| $B_2(\delta_0^2+\delta_1^2)$                                 | Table XIV, using nearest arguments             | 0.7                                |
| $B_2(\delta_0^2+\delta_1^2)$                                 | Error of $B_2$ from Table XV                   | 0.00011( $\delta_0^2-\delta_1^2$ ) |
| $B_3\delta_{\frac{3}{2}}^3+B_4(\delta_0^4+\delta_1^4)$       | Tables XVI and XVII, with mental interpolation | 0.3                                |
| $f_p$  | Final rounding error                           | 0.5                                |

## EXAMPLES

To find (a) the right ascension of the Sun, and (b) the horizontal parallax of the Moon, at 16<sup>h</sup> 23<sup>m</sup> 15<sup>s</sup>.8 E. T., on 1967 October 11. The tabular values, and their differences in units of the end figure of the functions, are:

| 1967 | R.A. of Sun | $\delta$ | $\delta^2$ | 1967 | H.P. of Moon | $\delta$ | $\delta^2$ | $\delta^3$ | $\delta^4$ |
|------|-------------|----------|------------|------|--------------|----------|------------|------------|------------|
| Oct. | h m s       |          |            | Oct. | ' "          |          |            |            |            |
| 10.0 | 12 58 57.39 | +22046   | +44        | 11.0 | 57 07.784    | -23038   | +1185      | +191       | -73        |
| 11.0 | 13 02 37.85 | +22091   | +45        | 11.5 | 56 44.746    | -21662   | +1376      | +131       | -60        |
| 12.0 | 13 06 18.76 | +22138   | +47        | 12.0 | 56 23.084    | -20155   | +1507      | +78        | -53        |
| 13.0 | 13 10 00.14 |          | +48        | 12.5 | 56 02.929    |          | +1585      |            | -45        |

(a) The tabular interval is one day; the interpolating factor  $p$  is therefore 0.68282. From Table XIII,  $B_2 = -0.054$ ; and

$$f_p = 13^h 02^m 37^s.85 + 0.68282(+220^s.91) - 0.054(+0^s.45 + 0^s.47) = 13^h 05^m 08^s.64$$

Alternatively, from Table XIV, with arguments  $p = 0.68$ ,  $\delta_0^2 + \delta_1^2 = 90$ , the second-difference correction  $B_2(\delta_0^2 + \delta_1^2) = -5$ ; and

$$f_p = 13^h 02^m 37^s.85 + 0.68282(+220^s.91) - 0^s.05 = 13^h 05^m 08^s.64$$

(b) The tabular interval is 0<sup>s</sup>.5; the interpolating factor  $p$  is therefore 0.36564. From Table XV,  $B_2 = -0.0580$ ; from Table XVI,  $B_3\delta_{\frac{1}{2}}^3 = +0.7$ , using  $p = 0.366$ ,  $\delta_{\frac{1}{2}}^3 = 131$ ; from Table XVII,  $B_4(\delta_0^4 + \delta_1^4) = -1.2$ , using  $p = 0.366$ ,  $\delta_0^4 + \delta_1^4 = 113$ ; and

$$f_p = 56' 44'' 746 + 0.36564(-21'' 662) - 0.0580(+1'' 376 + 1'' 507) + 0'' 0007 - 0'' 0012 = 56' 36'' 658$$

TABLE XIII. BESSEL COEFFICIENTS  $B_2, B_3, B_4$

Interpolating factor  $p$ : correction has same sign as difference  $(\delta_0^4 + \delta_1^4)$

$$f_p = f_0 + p\delta_{14} + B_2(\delta_0^2 + \delta_1^2) + B_3\delta_{14}^3 + B_4(\delta_0^4 + \delta_1^4)$$

## EXPLANATION

This explanation is limited to stating the precise meanings of the tabular quantities, and specifying the sources of the fundamental tables and constants used in calculating them. Complete explanations of the ephemerides and their computation are contained in a separate volume, *Explanatory Supplement to The Astronomical Ephemeris and The American Ephemeris and Nautical Almanac*, published by H. M. Stationery Office, London; it includes the formulae and the auxiliary tables with which the computations are made, and numerical examples of all the calculations.

Beginning with the volume for 1960, the tabular argument in the fundamental ephemerides of the Sun, Moon, and planets is Ephemeris Time; in nearly all of the other ephemerides, the argument is Universal Time. Ephemeris Time is the uniform measure of time defined by the laws of dynamics and determined in principle from the orbital motions of the planets, specifically the *orbital motion of the Earth* as represented by NEWCOMB's *Tables of the Sun*. Universal Time is defined by the *rotational motion of the Earth*, and is determined from the apparent diurnal motions which reflect this rotation; because of variations in the rate of the rotation, Universal Time is not rigorously uniform.

Ephemeris Time is the independent variable in the gravitational theories of the Sun, Moon, and planets. The Ephemeris Time at any instant is obtained from observation by directly comparing observed positions of the Sun, Moon, and planets with gravitational ephemerides of their coordinates; observations of the Moon are the most effective and expeditious for this purpose. An accurate determination, however, requires observations over a more or less extended period; in practice, it takes the form of determining the correction  $\Delta T$  that must be applied to Universal Time to obtain Ephemeris Time:

$$\text{E.T.} = \text{U.T.} + \Delta T.$$

The Universal Time at any instant may be obtained with little delay from observations of the diurnal motions; it is the basis of civil timekeeping, and is the standard in astronomical observation and in the applications of astronomy to navigation and surveying. Ephemeris Time is the standard for purposes that require a strictly uniform measure. In order to provide a *relatively* uniform measure without delay, determinations of Universal Time, beginning with 1956, have been corrected for the variation of the meridian due to the observed motion of the geographic poles, and for the extrapolated annual variation in the rate of rotation of the Earth; the corrected value is distinguished by the notation UT2.

The numerical measure in which Ephemeris Time is reckoned is defined by the apparent *annual motion of the Sun in longitude*. Universal Time, in

principle, is determined by the *average* rate of the apparent *diurnal motion of the Sun relative to the meridian of Greenwich*; but in practice, the numerical measure of Universal Time at any instant is computed from a conventional relation to the measure of time defined by the diurnal motion of the equinox or First Point of Aries, known as *sidereal time*. The sidereal time at any instant may be rapidly and accurately determined from observations of the diurnal motions of stars.

The sidereal time is numerically measured by the hour angle of the equinox, which represents the position of the equinox in its diurnal circuit. The period of one diurnal circuit of the equinox in hour angle, between two consecutive upper meridian transits, is a sidereal day; it is divided into 24 sidereal hours, reckoned from 0<sup>h</sup> at upper transit which is known as sidereal noon. The *true* equinox is at the intersection of the true equator of date with the ecliptic of date; the time measured by its diurnal motion is *apparent sidereal time*. The position of the true equinox is affected by the nutation of the axis of rotation of the Earth; and the nutation consequently introduces irregular periodic inequalities into the apparent sidereal time and the length of the sidereal day. The time measured by the diurnal motion of the *mean* equinox of date, which is affected only by the secular inequalities due to the precession of the axis, is *mean sidereal time*. Apparent sidereal time minus mean sidereal time is the *equation of the equinoxes* due to the nutation; in the volumes immediately preceding 1960, it was designated as the nutation in right ascension, and was included in the ephemeris of the Sun.

Universal Time is a particular case of the measure known in general as *mean solar time*. This measure is defined in principle by the apparent diurnal motion of a conventional fiducial point located on the mean celestial equator of date, and characterized by a uniform sidereal motion along the equator at a rate which only differs from the mean rate of the annual motion of the Sun along the ecliptic by the amount of the slight secular acceleration of the Sun. Relative to any meridian of longitude, this point has a diurnal motion in hour angle virtually the same as the average diurnal motion of the Sun, and with only very slight inequalities due to variations of the local meridian and variations of the rate of rotation of the Earth. The measure known as local mean solar time is derived from this fiducial point; but since the abstract point is not actually observable, the definition is formulated as a relation to sidereal time, and in practice mean solar time is obtained through this intermediary. Universal Time is the mean solar time on the Greenwich meridian, reckoned in days of 24 mean solar hours beginning with 0<sup>h</sup> at midnight.

The relation that defines the numerical measure of mean solar time is derived from the position adopted for the fiducial point relative to the equinox, which is represented by a conventional formula for its right ascension. The practice in the past has been to adopt for the right ascension an expression as nearly identical with the expression for the mean longitude of the Sun on the ecliptic as is possible, consistent with a sidereal motion at a constant rate. Due to the secular acceleration of the Sun and to the different secular accelerations of the equinox on the ecliptic and the equator, the position in right ascension

differs from the mean longitude of the Sun in Newcomb's *Tables* by only a slight progressively increasing excess of  $0^{\circ}0203 T^2$ , where  $T$  is the number of centuries after 1900. The position in hour angle is never more than about  $16^m$  from the Sun. This point, abstractly defined by the conventional expression for its right ascension, has therefore traditionally been called the fictitious mean sun. Its right ascension fixes its position among the stars at every instant, and is a means of exactly defining a measure of mean solar time by a relation to the sidereal time obtained from the observable diurnal motions of the stars.

This relation that defines mean solar time is expressed as a numerical formula for the sidereal time on the Greenwich meridian at the instant of mean midnight; the sidereal time calculated from this formula is the Greenwich hour angle of the equinox that *defines*  $0^h$  U.T. and enables this instant to be identified by observation. The formula that is in established use was derived by adding  $12^h$  to NEWCOMB's expression for the right ascension of the fictitious mean sun; the mean sidereal time at  $0^h$  U.T. of any calendar date is the numerical value of the resultant quantity

$$6^h 38^m 45^s.836 + 86\ 40184^s.542 T + 0^s.0929 T^2,$$

calculated with the value of  $T$  that denotes the number of Julian centuries of 36525 days which, at the midnight beginning the day, have elapsed since mean noon on 1900 January 0 at the Greenwich meridian. The instant at which the mean equinox reaches the Greenwich hour angle calculated from this formula is designated  $0^h$  U.T. Each mean solar day is the period of time between the two instants at which the equinox reaches the hour angles calculated with the two values of the parameter  $T$  at an interval of  $1/36525$  which denote consecutive dates.

Prior to the recognition of variations in the rotation of the Earth, mean midnight was considered to be the instant of lower meridian transit of the fictitious mean sun, since the formula is numerically the same as the expression for the right ascension of the fictitious mean sun increased by  $12^h$ . However, as a consequence of the variations in rotation, the motion of the equinox in hour angle is slightly irregular; but meanwhile, the rate of motion of the fictitious mean sun relative to the equinox is completely independent of the variable rotation of the Earth, and consequently the actual right ascension plus  $12^h$  does not reach the value calculated from a given value of  $T$  at exactly the *same instant* as does the hour angle of the equinox. The instant when the equinox reaches the calculated hour angle is midnight by definition; but the formula which represents the hour angle does not represent the right ascension of the mean sun plus  $12^h$  for *this same instant*, and this additional designation previously often used for the sidereal time of  $0^h$  has been eliminated from the ephemerides.

The sidereal and the mean solar measures are affected proportionally by the variations of the rotation; their ratio is a fixed constant, and the mean solar day is proportional to the period of rotation. The mean solar time at any instant on any meridian is determined from the observed local sidereal time at this instant by means of the constant ratio of the mean solar to the

sidereal measure, and the ephemeris of *Universal and Sidereal Times* on pages 10–17. The tabular sidereal times on successive dates are the Greenwich hour angles of the equinox that determine the instants of successive Greenwich mean midnights. At the instant of any observed Greenwich sidereal time, the interval which has elapsed since 0<sup>h</sup> U.T., expressed in sidereal units, is immediately obtained by subtracting the tabular sidereal time at 0<sup>h</sup> U.T. from the observed sidereal time at the instant. The Universal Time at the instant is the equivalent measure of this interval in units of mean solar time; it is obtained by multiplying the sidereal measure by the constant 0.99726 95664 which represents the ratio of the sidereal day to the mean solar day. The definition and practical determination of Universal Time were not affected by the introduction of Ephemeris Time in 1960, and the numerical reckoning was continued without discontinuity except for increased precision due to improved values of the nutation.

The ratio of the mean solar day to the mean sidereal day is 1.00273 79093, and the equivalent measures of the length of the day are:

Mean sidereal day . . . 23<sup>h</sup> 56<sup>m</sup> 04<sup>s</sup>.09054 of mean solar time

Mean solar day . . . . 24<sup>h</sup> 03<sup>m</sup> 56<sup>s</sup>.55536 of mean sidereal time

From these equivalents, Tables VIII and IX have been constructed for converting intervals of time from one measure to the other. To the order of accuracy of 0<sup>s</sup>.01, these tables may be used for either mean or apparent sidereal time; but in more precise calculations, separate account must be taken of the equation of the equinoxes.

### Calendar (Pages 1–3)

Over extended intervals, civil time is ordinarily reckoned according to conventional calendar years and adopted historical eras; in constructing and regulating civil calendars, and fixing ecclesiastical calendars, a number of auxiliary cycles and periods are used. The principal chronological eras and cycles are listed on page 1; and the Gregorian calendar for the current year is given on pages 2–3.

In astronomical practice prior to 1925, mean solar time was reckoned from noon instead of from midnight. The mean solar day beginning at noon, 12 hours *after* the midnight at the beginning of the same civil date, is known as the astronomical day. To facilitate chronological reckoning, the astronomical days beginning at Greenwich noon are numbered consecutively, from an epoch sufficiently far in the past to precede the historical period; the number which denotes a day in this continuous count is the Julian Day Number. The Julian Day reckoning begins with Julian Day Number 0 for January 1, 4713 B.C., Julian proleptic calendar; the Julian Day Number therefore denotes the length of time that has elapsed, at Greenwich noon at the beginning of the astronomical day, since this epoch. The Julian Day Numbers for the current year are given in the calendar; from Table I they may be found for other years up to A.D. 2300, and it is readily apparent how this table may be extended over any interval.

Dates expressed in Julian Days and fractions of a day represent time elapsed at the instant. In several of the ephemerides in this volume, the arguments are designated by the Julian Dates in addition to the Gregorian calendar dates. On pages where the argument is Ephemeris Time, the Julian Date, like the calendar date, refers to ephemeris days; but the Julian Day begins at 12<sup>h</sup> E.T., the calendar day at 0<sup>h</sup> E.T. The terminology *Julian Ephemeris Date* may be used to distinguish the Julian Date with the day beginning at 12<sup>h</sup> E.T. instead of at 12<sup>h</sup> U.T. (Greenwich Mean Noon), when it is essential to avoid ambiguity, as in dating orbital elements, or in formulae for light curves of variable stars, where the time must be given to a large number of decimals of a day.

The period of one complete circuit of the fictitious mean sun in right ascension, beginning at the instant when the right ascension is 18<sup>h</sup> 40<sup>m</sup>, is known as the Besselian solar year, and is an advantageous unit of time for some astronomical purposes. In 1967, the beginning of the Besselian year is January 1<sup>d</sup> 041 Ephemeris Time; this instant is denoted by the notation 1967.0, and is given at the foot of each page of the calendar. Because of the secular excess of the right ascension of the fictitious mean sun over the mean longitude of the Sun, the Besselian year is shorter than the tropical year by the amount 0<sup>s</sup>.148 *T*, where *T* denotes the time in centuries after 1900.

#### Phenomena (Pages 4–9)

The principal configurations of the Sun, Moon, and planets with one another during the year, and other phenomena of general interest, are listed on these pages.

The *Diary* on pages 5–7 contains, in chronological order with times to the nearest hour: the geocentric phenomena also given on page 4; occultations of the four bright stars *Aldebaran*, *Regulus*, *Spica*, and *Antares*, and of planets, for which, if any occur, another table is given on page 5 that includes the area of visibility, the tabular times being for geocentric conjunction in right ascension; and the dates of the eclipses and transits that occur during the year, for which the areas of visibility are indicated at the bottom of page 4. In addition, the *Diary* includes the phases of the Moon, and apogee and perigee of the Moon; the closest approach of Mars to the Earth, when the geocentric distance passes through a minimum; geocentric conjunctions in apparent right ascension of the planets with the Moon, with one another, and with the bright stars *Aldebaran*, *Pollux*, *Regulus*, *Spica*, and *Antares*, except when these phenomena occur within 24 hours of New Moon or within 10° of the Sun; and the geocentric phenomena of Ceres, Pallas, Juno, and Vesta, for which the dates alone are given at the bottom of page 8. The magnitudes and elongations from the Sun on every fifth day for the inferior planets and every tenth day for the superior planets, and approximate visual magnitudes of the minor planets Ceres, Pallas, Juno, and Vesta at 40-day intervals, are tabulated on pages 8–9. Revised values for the magnitudes of the minor planets were adopted, beginning with 1962.

The geocentric phenomena differ from the actually observed configurations by the effects of the geocentric parallax at the place of observation, which for configurations with the Moon may be quite large. The tabular times for the stationary points of the planets are the instants at which the planet is stationary in *apparent* geocentric right ascension; but for the elongations of the planets from the Sun, the tabular times are for the *geometric* configurations. The times of conjunction and opposition are, respectively, the instants when the apparent geocentric longitude of the planet differs by  $0^\circ$  and  $180^\circ$  from the geocentric longitude of the Sun. From inferior conjunction to superior conjunction of Mercury or Venus, or from conjunction to opposition of a superior planet, the elongation from the Sun is west; from superior to inferior conjunction, or from opposition to conjunction, the elongation is east. Because of the difference in latitude, the elongations do not in general pass through  $0^\circ$  or  $180^\circ$  as they change from west to east or from east to west. The tabular times of the greatest elongations of Mercury and Venus are the instants when the true geocentric angular distance from the Sun is a maximum.

The times of the equinoxes and solstices, which on page 4 are given to the nearest minute of Universal Time, are the instants when the apparent longitude of the Sun is a multiple of  $90^\circ$ .

The times given for the greatest brilliancy of Venus are the instants at which the value of the expression

$$\frac{(r + \Delta - R)(r + \Delta + R)}{r^3 \Delta^3}$$

is a maximum, where  $r$  and  $R$  denote, respectively, the heliocentric distances of Venus and the Earth, and  $\Delta$  is the geocentric distance of Venus.

The heliocentric phenomena for which dates are given on page 4 are the perihelion and aphelion, the passages through the nodes on the ecliptic, and the greatest north and south heliocentric latitudes, in the actual disturbed motion. Because of perturbations, the dates are not in general the same as the dates that would be obtained from the elements of the mean orbit; the date on which the radius vector is a minimum may differ considerably from the date on which the heliocentric longitude of the planet is equal to the longitude of the perihelion of the mean orbit, and similarly the heliocentric longitude of the planet when its heliocentric latitude becomes zero may differ from the longitude of the mean node. At the ascending node, the planet passes through the plane of the ecliptic from south to north, and the heliocentric latitude vanishes in changing from negative to positive; at the descending node, the latitude changes from positive to negative as the planet passes through the plane of the ecliptic from north to south.

#### Universal and Sidereal Times (Pages 10–17)

The sidereal time (Hour Angle of First Point of Aries) at  $0^h$  Universal Time, and the Universal Time at  $0^h$  sidereal time (Transit of First Point of Aries), are tabulated both for the mean equinox of date, and for the true equinox

with the short-period terms of nutation included. In the ephemeris of sidereal time at 0<sup>h</sup> U.T., the argument is the calendar date and the equivalent Julian Date. In the ephemeris of Universal Time at 0<sup>h</sup> sidereal time on each day, the argument is the Greenwich Sidereal Date, defined as the number of sidereal days, determined by the equinox of date, that have elapsed at Greenwich since the beginning of the sidereal day which was in progress at J.D. 0.0. The integral part of the Greenwich Sidereal Date is called the Greenwich Sidereal Day Number; it is a means of consecutively numbering the successive sidereal days beginning at the *transits* of the First Point of Aries, similar to the Julian Day reckoning of the successive mean solar days beginning at the instants of the *tabular hour angles* of the First Point of Aries. The Greenwich Sidereal Day is the number of sidereal days that have elapsed at 0<sup>h</sup> Greenwich sidereal time since the Greenwich sidereal 0<sup>h</sup> that immediately preceded J.D. 0.0; the zero day is the sidereal day that was in progress at the beginning of the Julian Era.

From these ephemerides for the meridian of Greenwich, the local mean time on any meridian of longitude may be calculated from the local sidereal time, or conversely. For this purpose, the longitude is expressed in time. The measure of longitude in arc may be converted to the equivalent measure in time by Table XII; the reverse transformation is obtained by Table XI.

The longitude expressed in time and reckoned positive westward is numerically the amount by which Universal Time is greater than the local mean solar time at the same instant. At the instant when the local mean time is 0<sup>h</sup>, the longitude is therefore the measure of the interval of mean solar time that has elapsed at Greenwich since 0<sup>h</sup> U.T.; and adding the equivalent measure of this mean solar interval in units of sidereal time to the Greenwich sidereal time at 0<sup>h</sup> U.T. gives the sidereal time at Greenwich at the instant when the mean solar time on the *local* meridian is 0<sup>h</sup>. Like the mean solar times, the Greenwich sidereal time is greater than the local sidereal time at the *same* instant by the amount of the longitude; and therefore the *local* sidereal time at 0<sup>h</sup> local mean solar time is obtained directly by adding to the tabular Greenwich sidereal time at the *previous* instant of 0<sup>h</sup> U.T. the same *correction* as required to convert the mean solar interval measured by the longitude into an equivalent sidereal interval. This reduction may either be taken from Table IX, or obtained by means of the hourly variation +9<sup>s</sup>8565.

Similarly, the Universal Time of Greenwich sidereal 0<sup>h</sup> may be reduced to the local mean solar time of 0<sup>h</sup> local sidereal time at any longitude by applying the correction from Table VIII, or by means of the hourly variation -9<sup>s</sup>8296.

#### *Conversion of sidereal time to mean solar time*

On 1967 July 7, at approximately 4<sup>h</sup> local mean solar time, in longitude 85° 15' west (+ 5<sup>h</sup> 41<sup>m</sup>), the observed apparent sidereal time is 23<sup>h</sup> 02<sup>m</sup> 11<sup>s</sup>.724. The Universal Time at this instant is approximately 10<sup>h</sup>; the equation of the

equinoxes is therefore  $-0^{\text{h}}53^{\text{m}}0$ , and subtracting this amount from the observed sidereal time gives the local mean sidereal time.

|   |   |
|---|---|
| Greenwich mean sidereal time, $0^{\text{h}}$ U.T., July 7 . . . . .   | <sup>h</sup> 18 <sup>m</sup> 57 <sup>s</sup> 06.235 |
| Reduction for longitude (Table IX). . . . .                           | + 56.018  |
| Mean sidereal time, $0^{\text{h}}$ local mean solar time. . . . .     | 18 58 02.253  |
| Local mean sidereal time at observation. . . . .                      | 23 02 12.254  |
| Sidereal interval since $0^{\text{h}}$ local mean solar time. . . . . | 4 04 10.001   |
| Reduction to mean solar interval (Table VIII). . . . .                | - 40.001  |
| Local mean solar time. . . . .  | 4 03 30.000   |

If the sidereal interval is less than  $3^{\text{m}} 56^{\text{s}}.5$ , there are two mean solar times corresponding to the sidereal time, one a few minutes after the preceding  $0^{\text{h}}$ , and the other a few minutes before the following  $0^{\text{h}}$ , at a mean solar time interval of about  $23^{\text{h}} 56^{\text{m}} 04^{\text{s}}$ . The approximate mean solar time always determines which one is to be taken. Any local sidereal time within an interval of less than  $3^{\text{m}} 56^{\text{s}}.5$  after  $0^{\text{h}}$  local mean solar time will occur a second time on the same mean solar day; the subtraction of the local sidereal time of  $0^{\text{h}}$  from either of these two sidereal times will give the same numerical result, but the actual interval for the second value is 24 sidereal hours greater.

The conversion of sidereal time to mean solar time may also be made by adding to the mean solar time of the *preceding* local sidereal  $0^{\text{h}}$  the equivalent of the sidereal time in units of mean solar time.

#### *Conversion of mean solar time to sidereal time*

To convert mean solar time to mean sidereal time, add to the local mean sidereal time at  $0^{\text{h}}$  the equivalent measure of the local mean solar time in sidereal units. To obtain the apparent sidereal time, add further the equation of the equinoxes, interpolated to the time. As an example, on 1967 July 7, in longitude  $85^{\circ} 15'$  west ( $+ 5^{\text{h}} 41^{\text{m}}$ ), at  $4^{\text{h}} 03^{\text{m}} 30^{\text{s}}$  local mean solar time, to determine the local sidereal time:

#### Sun, Moon, and Planets

In the fundamental ephemerides, except where otherwise stated, the tabular positions are *apparent* positions, i.e., the positions in which the Sun, Moon,

and planets would actually be seen from the center of the Earth at the tabular times, displaced by planetary aberration and referred to the coordinate systems determined by the instantaneous equator, ecliptic, and equinox, with Ephemeris Time as the argument; the value used for the light-time at unit distance is 498<sup>s</sup>.38, corresponding to the adopted constant of aberration. For comparison with photographic observations, *astrometric* positions are given for Pluto and the minor planets; for the latter they are included with the apparent positions. Ephemerides that are intended for theoretical purposes, where a fixed reference system is needed, are referred to the *fixed equinox* of a convenient epoch; and Tables III and IV are for facilitating reductions from one equinox to another.

The tabular quantities at instants other than the tabular times may be obtained by interpolation with the requisite order of differences. For this purpose, differences are included in many of the ephemerides; and Tables XIII–XVII may be used for interpolation.

The ephemerides are computed strictly from the tables to which references are made, and with the standard values that are stated for the fundamental constants. In accordance with resolutions of the International Astronomical Union, no corrections are applied to bring the tables into better accord with later observations, and no change has been made in the conventionally adopted value of any fundamental constant that was used in the volumes immediately preceding 1960. Tabular values, when taken from the same tables, are unaltered by the adoption of Ephemeris Time, but the tabular argument is correctly designated as Ephemeris Time instead of Universal Time.

Meridian transits, transit ephemerides and other phenomena that depend upon hour angles and geographic location, when calculated from the fundamental ephemerides by the same procedures as used prior to 1960, are referred, not to the Greenwich meridian and to Universal Time, but to a meridian 1.002738  $\Delta T$  east of the geographic meridian of Greenwich, and to Ephemeris Time. This slightly different meridian is known as the *ephemeris meridian*; to facilitate the calculation of phenomena that depend upon the rotation of the Earth, it is used as an auxiliary reference meridian. Hour angles and longitudes reckoned from the ephemeris meridian are distinguished by the terms *ephemeris hour angle* and *ephemeris longitude*. The ephemeris hour angle of the equinox is called *ephemeris sidereal time*.

The *ephemeris transit* is the Ephemeris Time at the instant of transit across the *ephemeris meridian*. Interpolation to any local meridian by using the ephemeris longitude as the interpolating factor gives the Ephemeris Time of local transit across this meridian; in forming first differences of the tabular ephemeris transits for this purpose, it must not be overlooked that the *day* is part of each tabular time. At ephemeris transit, the ephemeris sidereal time is equal to the right ascension.

When referred to the ephemeris meridian, phenomena depending on the rotation of the Earth may be calculated in terms of Ephemeris Time by methods which formally are exactly the same as the procedures for calculations referred

to the Greenwich meridian in terms of Universal Time. The practical calculations are based on the principle that the tabular Greenwich sidereal time of 0<sup>h</sup> U.T. is numerically equal to the ephemeris sidereal time of 0<sup>h</sup> E.T.; that is, the equinox at 0<sup>h</sup> E.T. is at the same hour angle from the ephemeris meridian as it is from the Greenwich meridian at 0<sup>h</sup> U.T.

Until  $\Delta T$  is known, local hour angles referred to a specific meridian of *geographic* longitude cannot be calculated; but the ephemeris longitude where the actual local hour angle has any particular value may be determined entirely in terms of Ephemeris Time, and this procedure is followed in predictions of the general circumstances of eclipses. As soon as  $\Delta T$  becomes known, the longitudes may be referred to the Greenwich meridian, and the Universal Times when the hour angle has the given values at these geographic longitudes may be determined.

For the computation of ephemerides with Universal Time as the argument, the value of  $\Delta T$  is specifically required. Since  $\Delta T$  depends primarily upon the *irregular* variations in the rate of rotation of the Earth, it cannot be determined in advance with certainty and exactness, or incorporated in the tables, but must be separately applied as determined from time to time by actual observation. Since ephemerides must be computed several years in advance, those that have the argument Universal Time are necessarily based upon an extrapolated value of  $\Delta T$ . However, the uncertainty of the extrapolation, over the relatively short intervals necessary, is within the order of accuracy to which these ephemerides are calculated; in practice, to the degree of precision needed, the ephemerides are for the most part unchanged by a transformation of the argument from Ephemeris Time to Universal Time.

Values of  $\Delta T$  as determined from discussions of observations are tabulated on page vii, together with estimated values for several later years.

The method of converting an ephemeris from Ephemeris Time to Universal Time depends upon whether hour angles are involved in the computation of the tabular quantities. When the tabular values are independent of the rotation of the Earth, an ephemeris for 0<sup>h</sup> Ephemeris Time may be converted to an ephemeris for 0<sup>h</sup> Universal Time by interpolating the tabular values to an interval  $\Delta T$  after 0<sup>h</sup> Ephemeris Time; if second differences are negligible, the interpolated values are obtained by adding algebraically to each of the tabular values for 0<sup>h</sup> Ephemeris Time the correction  $\frac{\Delta T}{h} \delta_{1/2}$ , where  $h$  is the tabular interval and  $\delta_{1/2}$  denotes the first difference.

The Universal Time of transit of the Sun, Moon, or a planet across the meridian of Greenwich may be found by subtracting  $\Delta T$  from the Ephemeris Time of Greenwich transit that is obtained by interpolating the ephemeris transit from the geographic longitude of the ephemeris meridian, 1.002738  $\Delta T$  east, to longitude 0°. The ephemeris transit is the time on the Greenwich meridian at the instant of transit across the ephemeris meridian; the Greenwich transit follows ephemeris transit at an interval which to a first approximation exceeds

$\Delta T$  by the time equivalent of the motion in right ascension during the interval  $\Delta T$ . The Universal Time of Greenwich transit is, therefore, algebraically greater than the tabular ephemeris transit by approximately the amount  $\frac{\Delta T}{h} \delta_{1/2} \alpha$ .

### *Fundamental Units and Astronomical Constants*

#### *Time, Mass, and Length*

The fundamental epoch from which Ephemeris Time is reckoned is the epoch that NEWCOMB designated as 1900 January 0, Greenwich Mean Noon, but which actually is 1900 January 0<sup>d</sup> 12<sup>h</sup> E.T.; the instant to which this designation is assigned is the instant near the beginning of the calendar year A. D. 1900 when the geometric mean longitude of the Sun referred to the mean equinox of date was 279°41'48".04 (*Trans. Int. Astr. Union*, vol. X, 1960, pages 72, 500). Ephemeris Time is the measure of time in which NEWCOMB's *Tables of the Sun* agree with observation.

The primary unit of Ephemeris Time is the tropical year, defined by the mean motion of the Sun in longitude at the epoch 1900 January 0<sup>d</sup> 12<sup>h</sup> E.T.; its length in ephemeris days is determined by the coefficient of  $T$  in NEWCOMB's expression for the geometric mean longitude of the Sun,  $L$ , referred to the mean equinox of date, given among the elements of the Sun. The *ephemeris second* is defined as 1/31556925.9747 of the tropical year for 1900 January 0<sup>d</sup> 12<sup>h</sup> E.T.; it has been formally adopted as the fundamental invariable unit of time by the Comité International des Poids et Mesures (*Procès-Verbaux des Séances*, deuxième sér. xxv, 77, 1957). The ephemeris day is 86400 ephemeris seconds. The former fundamental unit of time was the mean solar second, defined as 1/86400 of the mean solar day.

In the astronomical system of measures, the usual unit of time is the ephemeris day. The fundamental unit of mass is the mass of the Sun. The unit of length is the astronomical unit, defined as the unit of distance in terms of which, in KEPLER's Third Law  $n^2 a^3 = k^2(1 + m)$ , the semimajor axis  $a$  of an elliptic orbit must be expressed in order that the numerical value of the Gaussian constant  $k$  may be exactly 0.01720209895 when the unit of time is the ephemeris day (*Trans. Int. Astr. Union*, vol. VI, 1939, pages 20, 336, 357); in astronomical units, the mean distance of the Earth from the Sun, calculated by KEPLER's Law from the observed mean motion  $n$  and adopted mass  $m$ , is 1.0000 0003 (NEWCOMB).

*Annual rates of precession* (NEWCOMB, *Astr. Pap. Amer. Eph.*, VIII, 73, 1897)

|   |                                     |
|---|-------------------------------------|
| General precession . . . . .            | $p = 50''.2564 + 0''.0222\ T$       |
| Planetary precession . . . . .          | $\lambda' = 0''.1247 - 0''.0188\ T$ |
| Lunisolar precession . . . . .          | $\psi = 50''.3708 + 0''.0050\ T$    |
| Precession in right ascension . . . . . | $m = 3^s.07234 + 0^s.00186\ T$      |
| Precession in declination . . . . .     | $n = 20''.0468 - 0''.0085\ T$       |

The time  $T$  is measured in tropical centuries from 1900.0. The values of  $p$ ,  $m$ , and  $n$  at the beginning of the Besselian solar year are given on page 50.

These *rates* of the precessional motions at a particular epoch must be carefully distinguished from the accumulated *amounts* of the motions over an extended interval of time, and the consequent displacements of the coordinate systems which the precessional motions produce. The amount of the precession in right ascension during the interval of time from  $t_0$  to  $t$  is  $\zeta_0 + z$ , where  $90^\circ - \zeta_0$  is the right ascension of the ascending node of the mean equator at time  $t$  on the mean equator of  $t_0$  reckoned from the mean equinox of  $t_0$ , and  $90^\circ + z$  is the right ascension of the node reckoned from the mean equinox of  $t$ ; the amount of the precession in declination is the inclination  $\theta$  of the mean equator

at time  $t$  to the mean equator of  $t_0$ . For  $t_0 = 1950.0$ , with the interval of time  $T$  from this epoch measured in tropical centuries,

$$\begin{aligned}\zeta_0 &= +2304''.948 \ T + 0''.302 \ T^2 + 0''.0179 \ T^3, \\ z &= +2304''.948 \ T + 1''.093 \ T^2 + 0''.0192 \ T^3, \\ \theta &= +2004''.255 \ T - 0''.426 \ T^2 - 0''.0416 \ T^3.\end{aligned}$$

Interchanging  $t_0$  with  $t$  replaces  $\zeta_0$  by  $-z$ , and  $z$  by  $-\zeta_0$ , and changes the sign of  $\theta$ .

On page 50, the numerical values are given for these precessional displacements of the mean equator and mean equinox during the interval between 1950.0 and the beginning of the current year; and Table III contains values for other intervals. Over a short interval, the values of  $\zeta_0 + z$  and  $\theta$  may be obtained from the rates  $m$  and  $n$  of the precessions at the *midpoint of the interval*, by the formulae

$$M = m(t_0 - t), \quad N = n(t_0 - t).$$

Similarly, the amounts of the general precession in longitude  $a$ , and rotation of the ecliptic  $b$ , may be calculated from the rate of precession  $p$ , and speed of rotation of the ecliptic  $\pi$ , at the midpoint of the interval, by

$$a = p(t_0 - t), \quad b = \pi(t_0 - t).$$

The numerical values of these quantities for the interval between 1950.0 and the current year, and of

$$c = 180^\circ - \Pi + \frac{1}{2}a$$

where  $\Pi$  is the longitude of the axis of rotation of the ecliptic at the midpoint of the interval, are also given on page 50, with formulae for calculating the corresponding precessional variations of equatorial and ecliptic coordinates, and of the ecliptic elements  $\Omega$ ,  $i$ ,  $\omega$ , of an orbit. Expressions for calculating  $\pi$  and  $\Pi$  at any date are given among the elements of the Sun.

### *Nutation*

The formulae adopted for computing the nutation in longitude and obliquity are obtained by retaining all terms with coefficients as great as  $0''.0002$  from the expressions developed in *Astr. Pap. Amer. Eph.*, vol. XV, Part I, page 153, 1953; they are given in *Astr. Jour.*, 58, 2, 1953, and in the *Explanatory Supplement*.

The effects of short-period terms, defined as terms with periods of less than 35 days, are fully included in the ephemerides of the Sun, Moon, and planets.

### *Sun (Pages 18–50)*

The ephemerides of the Sun are derived from the geometric longitude referred to the mean equinox of date, the latitude referred to the ecliptic of date, the logarithm of the radius vector, and the mean obliquity of date, that

are taken from NEWCOMB'S *Tables of the Sun, Astr. Pap. Amer. Eph.*, vol. VI, Part I, 1895. The mean orbital elements on which these tables are based, with  $T$  denoting the time measured in Julian centuries of 36525 ephemeris days from the epoch, and  $d$  the time in ephemeris days, are:

$$\text{Epoch 1900 January 0.5 E.T.} = \text{J.D. 241 5020.0}$$

Geometric mean longitude, mean equinox of date

$$\begin{aligned} L &= 279^\circ 41' 48''.04 + 1296 \ 02768''.13 T + 1''.089 T^2 \\ &= 279^\circ 69668 + 0^\circ 98564 \ 73354 d + 0^\circ 000303 T^2 \end{aligned}$$

Mean longitude of perigee, mean equinox of date

$$\begin{aligned} \Gamma &= 281^\circ 13' 15''.0 + 6189''.03 T + 1''.63 T^2 + 0''.012 T^3 \\ &= 281^\circ 22083 + 0^\circ 00004 \ 70684 d + 0^\circ 000453 T^2 + 0^\circ 000003 T^3 \end{aligned}$$

Mean anomaly,  $L - \Gamma$

$$\begin{aligned} g &= 358^\circ 28' 33''.0 + 1295 \ 96579''.10 T - 0''.54 T^2 - 0''.012 T^3 \\ &= 358^\circ 47583 + 0^\circ 98560 \ 02670 d - 0^\circ 000150 T^2 - 0^\circ 000003 T^3 \end{aligned}$$

Eccentricity

$$e = 0.01675 \ 104 - 0.00004 \ 180 T - 0.00000 \ 0126 T^2$$

The principal related auxiliary constants are:

Mean obliquity of the ecliptic

$$\begin{aligned} \epsilon &= 23^\circ 27' 08''.26 - 46''.845 T - 0''.0059 T^2 + 0''.00181 T^3 \\ &= 23^\circ 452294 - 0^\circ 01301 \ 25 T - 0^\circ 00000 \ 164 T^2 + 0^\circ 00000 \ 0503 T^3 \end{aligned}$$

Annual rate of rotation of ecliptic  $\pi = 0''.4711 - 0''.0007 T$

Longitude of axis of rotation  $\Pi = 173^\circ 57'.06 + 54'.77 T$

Lengths of the years

|             |  |
|-------------|--|
| Tropical    | $365^d \ 2421 \ 9879 - 0^d 0000 \ 0614 T$  |
|             | $365^d \ 05^h \ 48^m \ 46^s.0 - 0^s.530 T$ |
| Sidereal    | $365^d \ 2563 \ 6042 + 0^d 0000 \ 0011 T$  |
|             | $365^d \ 06^h \ 09^m \ 09^s.5 + 0^s.01 T$  |

|             | $346^d \ 14^h \ 52^m \ 50^s.7 + 2^s.8 T$   |

The longitude of the axis of rotation of the ecliptic is for the extremity that is at the ascending node of the instantaneous position of the ecliptic on the immediately preceding position; and it is referred to the mean equinox of date. The position of the ecliptic in terms of its inclination  $\pi_1$  and node  $\Pi_1$  on the fixed ecliptic of the epoch is represented by

$$\begin{aligned} \pi_1 \sin \Pi_1 &= +4''.964 T + 0''.1939 T^2 - 0''.00019 T^3, \\ \pi_1 \cos \Pi_1 &= -46''.845 T + 0''.0545 T^2 + 0''.00035 T^3. \end{aligned}$$

The values of  $L$  and  $g$  for every tenth day, the values of  $\Gamma$  and  $e$  at the beginning of the calendar year, and of  $\pi$ ,  $\Pi$ , and  $\epsilon$  and the trigonometric functions of  $\epsilon$  for the beginning of the Besselian year, are given on page 50.

The geocentric spherical coordinates of the Sun are tabulated in the ephemeris on pages 18–33. The geocentric equatorial rectangular coordinates are given on pages 34–49, referred to the mean equator and equinox of both the beginning of the year and 1950.0; the dates in bold-face type are the standard 10-day ephemeris dates recommended by the International Astronomical Union, for which the integral part of the Julian Day Number is divisible by 10. The positive  $X$ -axis is directed toward the equinox, the  $Y$ -axis toward the point on the equator at right ascension  $6^h$ , and the  $Z$ -axis toward the north pole of the equator.

The tabular longitude is the geometric longitude referred to the mean equinox of the beginning of the Besselian year; it may be reduced to the fixed mean equinox of 1950.0 by applying the correction given in the footnote. The values of the latitude referred both to the ecliptic of the beginning of the year and to the fixed ecliptic of 1950.0 are tabulated, in addition to the latitude referred to the ecliptic of date.

The precession in longitude is the amount of the precessional displacement of the equinox along the ecliptic since the beginning of the Besselian year. Adding it to the tabular longitude gives the geometric longitude referred to the mean equinox of date, which may be further reduced to the true equinox of date by adding the nutation in longitude. The nutation includes short-period terms.

The reduction to apparent longitude is the sum of the nutation in longitude at date and the precession from the beginning of the year to date, diminished by aberration which is calculated by dividing  $20''.47$  by the radius vector.

The horizontal parallax is the angle subtended at the Sun by the equatorial radius of the Earth; the tabular values are calculated by dividing  $8''.80$  by the radius vector.

The apparent right ascension and declination are referred to the true equinox and equator of date, and are affected by aberration. They are calculated from the geometric longitude, the latitude referred to the ecliptic of date, and the tabular obliquity of date, which is the sum of the mean obliquity and the nutation in obliquity inclusive of short-period terms; they are corrected for aberration by antedating for the light-time. The value of the radius vector is geometric, not affected by aberration.

The tabular semidiameter includes an allowance for irradiation, and is obtained by dividing an enhanced value of the semidiameter at unit distance by the radius vector, although actually the irradiation does not depend upon the distance; the value adopted for the enhanced semidiameter at unit distance is  $16' 01''.18$ .

#### *Moon* (Pages 51–159)

The lunar ephemeris is calculated directly from BROWN's theory instead of from his *Tables of the Motion of the Moon*; but in order to obtain a strictly gravitational ephemeris expressed in the same measure of time as defined by

NEWCOMB'S *Tables of the Sun*, the orbital elements upon which BROWN'S tables are based are amended by removing the empirical term and by applying to the mean longitude the correction

$$-8^{\circ}.72 - 26^{\circ}.74 T - 11^{\circ}.22 T^2,$$

where  $T$  is measured in Julian centuries from 1900 January 0.5 E.T. = J.D. 2415020.0.

Denoting by  $d$  the number of ephemeris days from the epoch, the fundamental orbital constants are

$$\begin{aligned}\zeta &= 270^{\circ} 26' 02''.99 + 1336' 307^{\circ} 52' 59''.31 T - 4''.08 T^2 + 0''.0068 T^3 \\ &= 270^{\circ}.434164 + 13^{\circ}.17639 65268 d - 0^{\circ}.001133 T^2 + 0^{\circ}.0000019 T^3,\end{aligned}$$

$$\begin{aligned}\Gamma' &= 334^{\circ} 19' 46''.40 + 11' 109^{\circ} 02' 02''.52 T - 37''.17 T^2 - 0''.045 T^3 \\ &= 334^{\circ}.329556 + 0^{\circ}.11140 40803 d - 0^{\circ}.010325 T^2 - 0^{\circ}.000012 T^3,\end{aligned}$$

$$\begin{aligned}\Omega &= 259^{\circ} 10' 59''.79 - 5' 134^{\circ} 08' 31''.23 T + 7''.48 T^2 + 0''.008 T^3 \\ &= 259^{\circ}.183275 - 0^{\circ}.05295 39222 d + 0^{\circ}.002078 T^2 + 0^{\circ}.000002 T^3,\end{aligned}$$

$$e = 0.05490 0489,$$

$$\gamma = 0.04488 6967,$$

$$\text{Constant of sine parallax, } 3422''.5400,$$

where  $\gamma$  is the sine of half the inclination to the ecliptic,  $e$  denotes the eccentricity, and

$\zeta$ , the mean longitude of the Moon, measured in the ecliptic from the mean equinox of date to the mean ascending node of the lunar orbit, and then along the orbit;

$\Gamma'$ , the mean longitude of the lunar perigee, measured in the ecliptic from the mean equinox of date to the mean ascending node of the lunar orbit, and then along the orbit;

$\Omega$ , the longitude of the mean ascending node of the lunar orbit on the ecliptic, measured from the mean equinox of date.

The equatorial horizontal parallax at distance 60.2665 equatorial radii of the Earth is  $57' 02''.70$ .

In the lunar theory, the adopted ratio of the mass of the Earth to the mass of the Moon is 81.53.

The mean elongation of the Moon from the Sun is

$$\begin{aligned}D &= 350^{\circ} 44' 14''.95 + 1236' 307^{\circ} 06' 51''.18 T - 5''.17 T^2 + 0''.0068 T^3 \\ &= 350^{\circ}.737486 + 12^{\circ}.19074 91914 d - 0^{\circ}.001436 T^2 + 0^{\circ}.0000019 T^3.\end{aligned}$$

The lengths of the months for the epoch 1900 are

|                       | d          | d  | h  | m  | s    |
|-----------------------|------------|----|----|----|------|
| Synodic . . . . .     | 29.530 589 | 29 | 12 | 44 | 02.9 |
| Tropical . . . . .    | 27.321 582 | 27 | 07 | 43 | 04.7 |
| Sidereal . . . . .    | 27.321 661 | 27 | 07 | 43 | 11.5 |
| Anomalistic . . . . . | 27.554 551 | 27 | 13 | 18 | 33.2 |
| Draconitic . . . . .  | 27.212 220 | 27 | 05 | 05 | 35.8 |

The secular variations do not exceed a few hundredths of a second per century, and depend partly upon the variations in the rate of rotation of the Earth.

The values of  $\Gamma'$ ,  $\Omega$ ,  $\zeta$ , and  $D$  for every tenth day are tabulated on page

51. This page also contains, for every tenth day, the values of

$i$ , the inclination of the mean equator of the Moon to the true equator of the Earth,

$\Delta$ , the arc of the mean equator of the Moon from its ascending node on the true equator of the Earth to its ascending node on the ecliptic of date,

$\Omega'$ , the arc of the true equator of the Earth from the true equinox of date to the ascending node of the mean equator of the Moon,

calculated with HAYN'S value of  $1^\circ 32'.1$  for the inclination of the mean lunar equator to the ecliptic; the ascending node of the mean lunar equator on the ecliptic is at the descending node of the mean lunar orbit,  $\Omega \pm 180^\circ$ .

The longitude referred to the mean equinox of date, the latitude referred to the ecliptic of date, and the horizontal parallax (pages 52–67) are computed for every half-day from BROWN'S theoretical expressions, with the corrections required for the amendment to the mean longitude. The apparent longitude and latitude are obtained by adding the nutation in longitude and some residual effects of aberration not included in BROWN'S expressions. (*Astr. Jour.*, **57**, 46, 1952).

The semidiameter,  $s$ , is derived from the horizontal parallax,  $\pi$ , by the formula

$$s = 0''.0796 + 0.272446 \pi,$$

the constants in which are based on NEWCOMB'S value of  $15' 32''.58$  for the semidiameter at mean distance (Researches on the Motion of the Moon, Part II, *Astr. Pap. Amer. Eph.*, vol. IX, 39, 1912). No correction is made for irradiation.

The apparent right ascension and declination for each hour of Ephemeris Time (pages 68–159) are calculated for  $0^h$  and  $12^h$  from the apparent longitude, the apparent latitude, and the true obliquity of date; and for the other hours by interpolation.

Page 159 contains the phases of the Moon, and the times of perigee and apogee or least and greatest distances from the Earth. The times of New Moon, First Quarter, Full Moon and Last Quarter are the times at which the excess of the apparent longitude of the Moon over the apparent longitude of the Sun is  $0^\circ$ ,  $90^\circ$ ,  $180^\circ$ , and  $270^\circ$ , respectively. The lunations are numbered in continuation of E. W. BROWN'S series, of which No. 1 commenced on 1923 January 16 (*Mon. Not. Roy. Astr. Soc.*, **93**, 603, 1933).

#### *The Planets (Pages 160–257)*

The orbital longitudes and the heliocentric ecliptic longitudes referred to the mean equinox of date, the heliocentric latitudes referred to the ecliptic

of date, and the radii vectores of the *inner planets* Mercury, Venus, and Mars are taken from NEWCOMB'S tables in *Astr. Pap. Amer. Eph.*, vol. VI, Parts II, III, IV, 1895-1898; for Mars, the corrections derived by Ross, *Astr. Pap. Amer. Eph.*, vol. IX, Part II, 1917, are applied. The orbital elements are for the mean orbits. For Venus and Mars, the latitude referred to the mean orbit, due to periodic perturbations in latitude, is included in the heliocentric ephemerides.

The ephemerides of the *outer planets* Jupiter, Saturn, Uranus, Neptune, and Pluto, are computed from the heliocentric rectangular coordinates obtained by numerical integration in *Astr. Pap. Amer. Eph.*, vol. XII, 1951. Perturbations by the inner planets, taken from *Astr. Pap. Amer. Eph.*, vol. XIII, Part V, 1954, are included in the geocentric ephemerides, but are omitted from the heliocentric ephemerides, and from the heliocentric orbital elements. The elements are for the osculating orbits.

In these ephemerides, the adopted masses of the planets and the formulæ for the mean elements of the inner planets are given in the *Explanatory Supplement*.

The geocentric ephemerides are calculated from the heliocentric coordinates of the planets and the geocentric coordinates of the Sun. The *apparent* right ascension and declination are referred to the true equator and equinox of date, inclusive of the short-period terms of nutation; and they have been corrected for planetary aberration.

The *astrometric* positions of Pluto and the minor planets are obtained by adding the planetary aberration to the geometric ephemeris referred to a standard mean equinox such as that of 1950.0, and then subtracting stellar aberration, calculated by the conventional formula which neglects the part depending on the longitude of the perihelion of the Earth. The astrometric ephemeris is therefore rigorously comparable with observations that are referred to catalogue mean places of comparison stars (corrected for proper motion and annual parallax, if significant, to the epoch of observation), it being only necessary to correct the observations for geocentric parallax.

The tabular true distance from the Earth is the actual geocentric distance at the tabular time, *not* at the instant when the light that reaches the observer at the tabular time left the planet.

The horizontal parallax is  $8''.80$  divided by the geocentric distance. The tabular semidiameter is the value at unit distance divided by the geocentric distance; the adopted semidiameters at unit distance are:

|                      |        |                      |        |
|----------------------|--------|----------------------|--------|
| Mercury . . . . .    | 3''34  | Saturn:              |        |
| Venus . . . . .      | 8''41  | Equatorial . . . . . | 83''33 |
| Mars. . . . .        | 4''68  | Polar . . . . .      | 74''57 |
| Jupiter:             |        | Uranus . . . . .     | 34''28 |
| Equatorial . . . . . | 98''47 | Neptune . . . . .    | 36''56 |
| Polar. . . . .       | 91''91 |                      |        |

The authorities for these values are given in the *Explanatory Supplement*.

The ephemerides of the minor planets Ceres, Pallas, Juno, and Vesta are computed from heliocentric rectangular coordinates calculated by PAUL HERGET, *Astr. Pap. Amer. Eph.*, vol. XVI, Part III, 1962.

The ephemerides are in the same form as for Pluto, with the addition of the reductions from astrometric to apparent right ascension and declination. Daily positions are given for the periods during which the planet is more than about  $40^\circ$  from the Sun. Since accurate observations of the minor planets may lead to an improved value for the mass of the Moon, the dates on which the lunar inequality is a maximum in right ascension are indicated by an asterisk. The magnitudes are *photographic*; revised values were adopted, beginning with 1962.

### Stars

The star places that are given in this volume are limited to the mean places of the brighter stars at the beginning of the Besselian year, to an accuracy of  $0.1$  in right ascension and  $1''$  in declination. However, the volume contains all the data necessary for the accurate reduction of precise star places from one epoch to another, or from mean place to apparent place. Examples of these reductions are given in the *Explanatory Supplement*.

### Day Numbers (Pages 258–281)

The Besselian Day Numbers and the Independent Day Numbers are given for  $0^h$  Ephemeris Time, with the sidereal time to the nearest tenth of an hour to assist in determining the interpolating factor for the time of meridian transit of a star. They are followed by the Besselian Day Numbers at  $0^h$  Greenwich sidereal time; these are derived quantities, and the third decimal is uncertain by one unit.

From these Day Numbers, the reduction from mean place to apparent place for precession, nutation, and aberration is obtained to the first order. The additional Day Numbers necessary to determine the reduction to the second order, tabulated separately for northern and southern declinations, are given on pages 278–281.

To avoid a second-order reduction as far as possible, the Day Numbers are referred to the *nearest* beginning of a year, instead of always to the beginning of the current year. For any tabular date,  $\tau$  denotes the fraction of a tropical year that has elapsed since the date to which the tabular values of the Day Numbers are referred; and the apparent place is obtained with these Day Numbers from the mean place at the beginning of either the *current* Besselian year or the *next following* year, according to the tabular value of  $\tau$ . In consequence, all the Day Numbers except  $B$  and  $E$  are discontinuous at the middle of the year; for July 1 and 2, values are given for both epochs. By not extending the reduction over more than half a year,

the second-order reduction and the error from neglecting it are kept as small as practicable.

The reductions to the second order, including the proper motion, are

$$\begin{aligned}\alpha &= \alpha_0 + \tau\mu_\alpha + Aa + Bb + Cc + Dd + E + J \tan^2 \delta_0 \\ &= \alpha_0 + \tau\mu_\alpha + f + g \sin (G + \alpha_0) \tan \delta_0 + h \sin (H + \alpha_0) \sec \delta_0 + J \tan^2 \delta_0, \\ \delta &= \delta_0 + \tau\mu_\delta + Aa' + Bb' + Cc' + Dd' + J' \tan \delta_0 \\ &= \delta_0 + \tau\mu_\delta + g \cos (G + \alpha_0) + h \cos (H + \alpha_0) \sin \delta_0 + i \cos \delta_0 + J' \tan \delta_0,\end{aligned}$$

where zero subscripts denote the mean place, and

$$\begin{aligned}a &= \frac{m}{n} + \sin \alpha_0 \tan \delta_0, & a' &= \cos \alpha_0, \\ b &= \cos \alpha_0 \tan \delta_0, & b' &= -\sin \alpha_0, \\ c &= \cos \alpha_0 \sec \delta_0, & c' &= \tan \epsilon \cos \delta_0 - \sin \alpha_0 \sin \delta_0, \\ d &= \sin \alpha_0 \sec \delta_0, & d' &= \cos \alpha_0 \sin \delta_0,\end{aligned}$$

which are known as the Besselian Star Constants. Additional corrections for parallax may be obtained from

$$\begin{aligned}\Delta\alpha &= \pi (cY - dX), \\ \Delta\delta &= \pi (c'Y - d'X),\end{aligned}$$

where  $X, Y$  are the coordinates of the Sun and  $c, d, c', d'$  are the Besselian Star Constants. In the case of binary stars, a correction for orbital motion may be necessary. The tabular values of the Day Numbers  $A, B, C, D, g, h, i$ , are in seconds of arc; when used for reducing right ascension, either they or the Star Constants by which they are multiplied must be divided by 15 to express the reduction in seconds of time.

The Besselian Day Numbers  $A, B$ , and  $E$ , or the Independent Day Numbers  $f, g$ , and  $G$ , give the reduction for precession and nutation. The short-period terms of nutation in longitude and obliquity,  $d\psi$  and  $d\epsilon$ , respectively, and the Day Numbers  $f', g', G'$ , for obtaining the effects of these terms alone, are also tabulated. The Day Numbers  $f', g', G'$  are defined as:

$$\begin{aligned}f' &= +d\psi \cos \epsilon \\ g' \sin G' &= -d\epsilon \\ g' \cos G' &= +d\psi \sin \epsilon\end{aligned}$$

The Day Numbers  $C$  and  $D$ , or  $H, h$ , and  $i$ , give the reduction for aberration; they are derived from the actual disturbed velocity of the Earth referred to the center of mass of the solar system.

The Besselian Day Numbers are the most expeditious means of reduction when several apparent positions of the same star are required, or when the values of the Besselian Star Constants are already available; otherwise, the Independent Day Numbers are the more convenient.

Reductions for precession and nutation directly from the standard equinox of 1950.0 to the true equinox of date may be obtained with sufficient accuracy for a finding ephemeris of a comet or a minor planet by means of Table IV, in accordance with the formulae at the foot of the table. The tabular dates are the midnights following an integral Julian Date that is exactly divis-

ible by 10, in accordance with the resolutions of the International Astronomical Union that the osculation epochs of elements of comets and minor planets should be Julian Dates with the integral part divisible by 400, and that ephemerides should be for 10-day intervals. Dates followed by an asterisk are the Julian Dates with integral part divisible by 40.

To facilitate the reduction of observations in which the differences of right ascension and declination between two celestial objects are measured, the differential aberration and the differential precession and nutation may be determined from Tables V and VI in accordance with the precepts given with the tables. With the position of a star reduced to the equinox of 1950.0, or to the equinox of the nearest beginning of a year, the coordinates of an object referred to the same equinox are obtained by adding to the coordinates of the star the observed differences in the sense "object minus star", and the differential aberration, precession, and nutation taken from these tables.

#### *Mean Places of Stars (Pages 282-292)*

Mean places at the beginning of the Besselian year are tabulated for 1078 stars, including stars to a limiting magnitude 4.75 excepting 8 stars each within 30" of an included star; variable stars are in general included if the maximum is brighter than magnitude 4.7. The positions are taken from the Albany *General Catalogue of 33342 Stars for the Epoch 1950, 1937*. Beginning with 1965, the stars are tabulated in the order of their mean right ascensions at the epoch 1970.0. In the name of the star, the three-letter abbreviations for constellation names recommended by the International Astronomical Union are used; a list of these abbreviations is given in the *Explanatory Supplement*.

Disregarding proper motion, which is generally much less than a second of arc per year, the mean places at other epochs may be obtained by a reduction for precession alone. In particular, to obtain the mean place at the beginning of the next following year, which is required for calculating reductions from mean to apparent places with the tabular Day Numbers during the latter half of the current year, add to the tabular coordinates the reductions

$$\begin{aligned}\Delta\alpha &= m + n \sin \alpha \tan \delta, \\ \Delta\delta &= n \cos \alpha,\end{aligned}$$

where the values of  $m$  and  $n$  are taken from page 50. Formulae and constants for the reduction of right ascension and declination, and of longitude and latitude, for precession from the beginning of the current year to 1950.0 and in the reverse direction, are also given on page 50; and an extended tabulation of the equatorial precessional constants for other intervals is given in Table III.

Table III contains the reduction constants  $\zeta_0$ ,  $z$ , and  $\theta$  for rigorous trigonometric reductions of mean places to the beginning of the current year from the beginning of each fifth previous year back to 1755; and also the coefficients  $M$  and  $N$  for approximate reductions with the formulae on page 50. The table is calculated from formulae derived from NEWCOMB'S numerical expressions for the precessional displacements of the mean equator, *Astr. Pap. Amer. Eph.*,

vol. VIII, page 75, 1897;  $M$  and  $N$  are obtained from the rates of change of  $z + \zeta_0$  and  $\theta$  at the time midway from  $t_0$  to  $t$ . With the tabular constants, rigorous reductions of the coordinates  $\alpha_0, \delta_0$ , referred to the mean equinox of  $t_0$ , to the coordinates  $\alpha, \delta$ , referred to the mean equinox of the beginning of the current year, may be calculated from the formulae

$$\begin{aligned} q &= \sin \theta [\tan \delta_0 + \cos (\alpha_0 + \zeta_0) \tan \tfrac{1}{2} \theta], \\ \tan (\Delta\alpha - \mu) &= \frac{q \sin (\alpha_0 + \zeta_0)}{1 - q \cos (\alpha_0 + \zeta_0)}, \\ \mu &= \zeta_0 + z, \\ \alpha &= \alpha_0 + \Delta\alpha, \\ \tan \tfrac{1}{2} (\delta - \delta_0) &= \tan \tfrac{1}{2} \theta \sec \tfrac{1}{2} (\Delta\alpha - \mu) \cos [(\alpha_0 + \zeta_0) + \tfrac{1}{2} (\Delta\alpha - \mu)]. \end{aligned}$$

### Eclipses (Pages 293–299)

Elements and general circumstances are given for all solar and lunar eclipses, including penumbral lunar eclipses, which occur during the year. For solar eclipses, maps are given from which approximate local circumstances may be obtained for any particular place; and the Besselian elements are tabulated at 10-minute intervals for the calculation of accurate predictions for any point on or above the surface of the Earth. For total or annular eclipses the latitudes and longitudes of points on the central line and on the northern and southern limits, together with the duration of the total or annular phase and the altitude of the Sun on the central line, are tabulated at intervals of five minutes or less throughout the eclipse. For lunar eclipses, the circumstances and their Ephemeris Times or Universal Times are the same for all parts of the Earth; any particular phase is visible from the hemisphere over which the Moon is then above the horizon.

The elements and circumstances are computed in accordance with BESSEL'S method, for the International Ellipsoid, from apparent right ascensions and declinations of the Sun and Moon which include the short-period terms of nutation; and the coordinates of the Sun for this purpose are calculated to an additional decimal. The semidiameters of the Sun and Moon used in the calculation of eclipses do not include irradiation. The adopted semidiameter of the Sun at unit distance is  $15' 59''.63$  (AUWERS, *Astronomische Nachrichten*, 3068, 367, 1891), the same, except for irradiation, as in the ephemeris of the Sun. In calculating the duration of *total* solar eclipses on the central line, the apparent semidiameter of the Moon is obtained by putting its sine equal to  $0.272274 \sin \pi$ , where  $\pi$  is the horizontal parallax; but beginning with 1963, the adopted semidiameter of the Moon in *all other eclipse calculations* is  $0.272446 \pi + 0''.079$ . To obtain the tabular duration of the total phase, the correction  $+0.000 207$  must be applied to the tabular radius of the umbra.

In the calculation of lunar eclipses, the radius of the geometric shadow of the Earth is increased by one-fiftieth part to allow for the effect of the atmos-

phere. Otherwise, refraction is neglected in computing solar and lunar eclipses. The Besselian elements do not involve refraction. The circumstances of eclipses are calculated for the surface of the ellipsoid, and the inclusion of refraction in them would be inappropriate. For local predictions, corrections for refraction are unnecessary; they are required only in precise comparisons of theory with observation, in which many other refinements are also necessary.

The magnitude of a solar eclipse is the fraction of the solar diameter obscured by the Moon at greatest phase, measured along the common diameter. The magnitude of a lunar eclipse is the fraction of the lunar diameter obscured by the shadow of the Earth at greatest phase, measured along the common diameter.

On the solar eclipse maps, the curves drawn in long dashes indicate the times halfway between first and last contacts of the penumbra. These times of the middle of the eclipse should not be confused with the times of greatest eclipse, from which they may differ by several minutes. The curves drawn in short dashes give the semiduration of the partial phase. The Ephemeris Times of first and last contacts are derived from the time of middle by respectively subtracting and adding the semiduration. The curves are extended across the rising and setting limits of the eclipse, although part of the phenomenon occurs below the horizon for observers in those regions.

The Besselian elements characterize the geometric position of the shadow of the Moon relative to the Earth. The exterior tangents to the surfaces of the Sun and the Moon form the umbral cone, the interior tangents the penumbral cone. The common axis of the two cones is the axis of the shadow. The geocentric plane perpendicular to the axis of the shadow is called the fundamental plane, and is taken as the  $xy$ -plane of a system of geocentric rectangular coordinates. The  $x$ -axis is the intersection of the fundamental plane with the plane of the equator, and is directed positively toward the east; the  $y$ -axis is directed positively toward the north. The  $z$ -axis is parallel to the axis of the shadow, and is positive toward the Moon. The tabular  $x$  and  $y$  are the coordinates of the intersection of the axis of the shadow with the fundamental plane, in units of the equatorial radius of the Earth. The declination  $d$  and ephemeris hour angle  $\mu$  of the point on the celestial sphere toward which the axis of the shadow is directed represent the direction of the axis.

The radius of the penumbral cone on the fundamental plane is denoted by  $l_1$ ; the radius of the umbral cone is  $l_2$ , and is regarded as positive for an annular eclipse, negative for a total eclipse. The angles  $f_1$  and  $f_2$  are the angles which the elements of the penumbral and the umbral cones, respectively, make with the axis of the shadow.

To predict accurate local circumstances, calculate the geocentric coordinates  $\rho \sin \phi'$  and  $\rho \cos \phi'$  from the geodetic latitude  $\phi$  and longitude  $\lambda$ , with Table VII; the inclusion of the elevation above sea level in this calculation is all that is necessary to obtain the local circumstances at high altitudes or in the ionosphere. Obtain approximate times for the beginning, middle, and end of the eclipse from the eclipse map; and for each of these three times, take from the table of Besselian elements the values of  $x$ ,  $y$ ,  $\sin d$ ,  $\cos d$ ,  $\mu$ ,

and  $l_1$ , except that for the middle  $l_2$  is needed instead of  $l_1$  where the eclipse is total or annular. The hourly variations  $x'$ ,  $y'$ , of  $x$  and  $y$  are needed, and may be obtained with sufficient accuracy by multiplying the first differences of the tabular values by 6.

For each of the three approximate times, calculate the coordinates  $\xi$ ,  $\eta$ ,  $\zeta$  of the observer, and the hourly variations  $\xi'$ ,  $\eta'$ , from

$$\begin{aligned}\xi &= \rho \cos \phi' \sin h, \\ \eta &= \rho \sin \phi' \cos d - \rho \cos \phi' \sin d \cos h, \\ \zeta &= \rho \sin \phi' \sin d + \rho \cos \phi' \cos d \cos h, \\ \xi' &= \mu' \rho \cos \phi' \cos h, \\ \eta' &= \mu' \xi \sin d - \zeta d',\end{aligned}$$

where

$$h = \mu - \lambda - 1.0027 \Delta T.$$

Next, calculate

$$\begin{aligned}u &= x - \xi, & u' &= x' - \xi', \\ v &= y - \eta, & v' &= y' - \eta', \\ L &= l - \zeta \tan f, & n^2 &= u'^2 + v'^2, & (n > 0) \\ \Delta &= \frac{1}{n} (uv' - u'v), & D &= uu' + vv',\end{aligned}$$

$$\sin \psi = \frac{\Delta}{L}.$$

Neglecting the variation of  $L$ , the correction  $\tau$  to the assumed time of middle to obtain the *Ephemeris Time of greatest phase* is

$$\tau = -\frac{D}{n^2},$$

which may be expressed in minutes by multiplying by 60.

The correction  $\tau$  to the assumed times of beginning, middle and end to obtain the *Ephemeris Times of contacts* is

$$\tau = \frac{L}{n} \cos \psi - \frac{D}{n^2},$$

which may be expressed in minutes by multiplying by 60.

The ambiguity in the quadrant of  $\psi$  is removed by noting that  $\cos \psi$  must be negative for the beginning of the eclipse, for the beginning of the annular phase, and for the end of the total phase, and that  $\cos \psi$  must be positive for the end of the eclipse, the end of the annular phase and the beginning of the total phase.

If the eclipse is partial at the place, the quantities  $l_2$ ,  $L_2$  and  $\sin \psi$  will not be needed for the time of middle.

For greater accuracy, the times resulting from the calculation outlined above should be taken in place of the original approximate times, and a second approximation performed.

The adopted value of  $\Delta T$  must be subtracted from the final times to obtain the Universal Times of contacts and greatest phase.

The *magnitude of greatest partial eclipse*, in units of the solar diameter, is

$$M_1 = \frac{L_1 - \Delta}{2L_1 - 0.5464},$$

where the absolute value of  $\Delta$  is used.

The *magnitude of the central phase*, in the same units, is

$$M_2 = \frac{0.5464}{2L_1 - 0.5464}.$$

In order to obtain the *position angle of a point of contact*, calculate the angle  $N$  defined by

$$\cot N = \frac{v'}{u'},$$

$\sin N$  having the same algebraic sign as  $u'$ . The position angle  $P$  of the point of contact, reckoned from the north point of the solar limb toward the east, is

$$P = N + \psi,$$

where the results of the final approximation are used.

The position angle  $V$  of the point of contact, reckoned from the vertex of the solar limb toward the east is

$$V = P - C,$$

where  $C$ , the parallax angle, is obtained with sufficient accuracy from

$$\tan C = \frac{\xi}{\eta},$$

$\sin C$  having the same algebraic sign as  $\xi$ , and the results of the final approximation again being used.

At any locality within several miles of a point for which the preceding computation has been made, the Ephemeris Times of the phases may be obtained by computing differential corrections in which most of the necessary numerical quantities are already available from the previous calculations. Examples illustrating the calculation of the local circumstances of partial, total, and annular eclipses, and the calculation of differential corrections, are given in the *Explanatory Supplement*.

### Ephemerides for Physical Observations

The ephemerides for physical observations of the Sun, Moon, and planets are based on the fundamental ephemerides in the preceding part of the volume, and on the additional data to which specific references are made. The tabular values are affected by aberration, and should therefore be interpolated to the actual time of observation; but they are strictly geocentric. They are given to a degree of accuracy sufficient for the reduction of observations; any significant approximations made in their calculation are stated.

The value of the light-time for unit distance used in calculating the physical ephemerides is 498<sup>s</sup>.58, corresponding to the adopted values of the solar parallax and velocity of light. The stellar magnitudes of the planets are obtained from the formulae of G. MÜLLER, *Publicationen des Astrophysikalischen Observatoriums zu Potsdam*, 8, 366, 1893; the diameters of the planets are calculated from the same semidiameters at unit distance as in the fundamental ephemerides.

*Ephemeris for Physical Observations of the Sun* (Pages 300–305)

This ephemeris is calculated from the elements determined by CARRINGTON, *Observations of the Spots on the Sun*, 1863, pages 221, 244:

Inclination of the solar equator to the ecliptic,  $7^{\circ} 15'$ ;

Longitude of the ascending node of the solar equator on the ecliptic,  
 $73^{\circ} 40' + 50''.25 t$ , where  $t$  is the time in years reckoned from 1850;

Sidereal period of rotation, 25.38 mean solar days.

In the ephemeris,  $P$  denotes the position angle of the northern extremity of the axis of rotation, measured eastward from the north point of the disk;  $B_0$ , the heliographic latitude, and  $L_0$ , the heliographic longitude, of the central point of the disk. Heliographic longitudes on the surface of the Sun are measured from the solar meridian that passed through the ascending node of the solar equator on the ecliptic on 1854 January 1, Greenwich mean noon (J. D. 239 8220.0); they are reckoned from  $0^{\circ}$  to  $360^{\circ}$ , in the direction of rotation, i. e., westward on the apparent disk as viewed on the celestial sphere. CARRINGTON's zero meridian passed the ascending node twelve hours earlier.

The synodic period of rotation is the interval of time during which  $L_0$  decreases by  $360^{\circ}$ . The mean synodic period is  $27^d 2753$ . The beginning of each synodic rotation is the instant at which  $L_0$  passes through  $0^{\circ}$ ; the rotations are numbered in continuation of CARRINGTON's Greenwich photo-heliographic series, of which No. 1 commenced on 1853 November 9.

In computing the physical ephemeris of the Sun, no allowance for the secular motion of the ecliptic is made in the values of the elements; and the latitude of the Sun is neglected. No correction is applied to  $L_0$  for rotation during the light-time, since presumably it is already included in CARRINGTON's meridian; CARRINGTON, in reducing his observations, added  $20''$  for aberration to the tabular longitude of the Sun taken from the *Nautical Almanac*, but he appears to have referred his measurements to the *apparent* central point of the disk. By using the apparent longitude of the Sun in calculating the physical ephemeris, the aberration in longitude is included. No further correction for aberration is required.

*Ephemeris for Physical Observations of the Moon* (Pages 306–313)

In the computation of this ephemeris, the formulae and constants for the physical librations, and the value  $1^{\circ} 32' 1''$  for the inclination of the mean lunar equator to the ecliptic, that were determined by HAYN, *Abh. d. Math.-phys. Kl. d. K. Sächs. Ges. d. Wiss.*, XXX, page 49, 1907, have been used. The ephemeris is calculated from the apparent coordinates of the Moon and the Sun, and therefore aberration is fully included, excepting the inappreciable difference between the light-time from the Sun to the Moon and from the Sun to the Earth.

The *Age* is the number of days elapsed since the previous New Moon. The *Fraction Illuminated* is the fraction of the area of the lunar disk that is illuminated, and is equal to the illuminated fraction of the diameter perpendicular to the line of cusps.

On the surface of the Moon, selenographic longitudes are measured from the lunar meridian that passes through the mean central point of the visible disk, positive in the direction towards *Mare Crisium*, i. e., towards the west on the celestial sphere. Selenographic latitudes are reckoned positive towards the north limb; that is, they are positive in the hemisphere containing *Mare Serenitatis*. The mean central point of the disk is defined as the point on the lunar surface where the surface is intersected by the radius of the Moon that would be directed towards the center of the Earth, were the Moon to be at the mean ascending node when the node coincided with either the mean perigee or mean apogee.

The tabular selenographic longitude and latitude of the Earth are the geocentric selenographic coordinates of the apparent central point of the disk; at this point on the surface of the Moon, the Earth is in the selenocentric zenith. These coordinates are the sums of the geocentric optical and physical librations in longitude and latitude respectively. When the libration in longitude, or selenographic longitude of the Earth, is positive, the mean central point of the disk is displaced eastward on the celestial sphere, exposing to view a region on the west limb. When the libration in latitude, or selenographic latitude of the Earth, is positive, the mean central point of the disk is displaced towards the south, and a region on the north limb is exposed to view.

The selenographic coordinates of the point on the lunar surface where the Sun is in the selenocentric zenith are the selenographic longitude and latitude of the Sun. Subtracting the selenographic longitude of the Sun from  $90^\circ$  or  $450^\circ$  gives the selenographic *colongitude* of the Sun tabulated in the ephemeris; numerically, it is the *east* selenographic longitude of the morning terminator, and is therefore approximately  $270^\circ$ ,  $0^\circ$ ,  $90^\circ$ , and  $180^\circ$  at New Moon, First Quarter, Full Moon and Last Quarter, respectively. The longitude of the evening terminator differs by  $180^\circ$  from that of the morning terminator.

The position angle of the axis is the angle that the lunar meridian through the apparent central point of the disk towards the north lunar pole forms with the declination circle through the central point, reckoned eastward from the north point of the disk.

The column headed *Position Angle—Bright Limb* contains the position angles of the midpoint of the illuminated limb, reckoned eastward from the north point of the disk. The position angle of the terminator, defined as the position angle of the northern cusp, always lies between  $-90^\circ$  and  $+90^\circ$ ; before Full Moon it is  $90^\circ$  greater, after Full Moon  $90^\circ$  less, than the position angle of the midpoint of the bright limb.

For precise reductions of observations, the tabular librations and position angles of the axis should be reduced to topocentric values. For this purpose, the following differential corrections may be used (ATKINSON, *Mon. Not. Roy. Astr. Soc.*, **111**, 448, 1951). The geocentric zenith distance of the Moon,  $z$ , the parallactic angle  $Q$ , and the topocentric parallax  $\pi'$  are calculated from the geocentric right ascension, declination, and parallax of the Moon, the latitude  $\phi$  of the observer, and the local sidereal time, with the following formulae,

where  $h$  is the local hour angle of the Moon and either of the two formulae for  $Q$  may be used:

$$\begin{aligned}\cos z &= \sin \phi \sin \delta + \cos \phi \cos \delta \cos h, \\ \sin Q &= \sin h \cos \phi \operatorname{cosec} z, \\ \cos Q &= \frac{\sin \phi - \cos z \sin \delta}{\sin z \cos \delta}, \\ \pi' &= \pi (\sin z + 0.0084 \sin 2z).\end{aligned}$$

The corrections to the tabular selenographic longitude  $l$  and latitude  $b$  of the Earth and the position angle  $C$  of the axis are

$$\begin{aligned}\Delta l &= -\pi' \sin (Q - C) \sec b, \\ \Delta b &= +\pi' \cos (Q - C), \\ \Delta C &= +\sin (b + \Delta b) \Delta l - \pi' \sin Q \tan \delta.\end{aligned}$$

The tabular values should be interpolated to the time of observation with second differences.

#### *Disks of Mercury and Venus (Pages 314–315)*

The phase,  $k$ , is the ratio of the area of the illuminated portion of the apparent disk to the area of the entire apparent disk regarded as circular.

The phase angle,  $i$ , is the planetocentric angle between the Sun and the Earth.

The angle  $\Theta$  is the position angle of the midpoint of the bright limb, measured eastward from the north point of the disk.

The quantity  $L$ , conventionally called the brilliancy of the disk, is the numerical value of  $ks^2/r^2$ , where  $r$  is the radius vector from the Sun to the planet in astronomical units,  $s$  is the apparent semidiameter in seconds of arc, and  $ks^2$  is the illuminated area of the apparent disk in units of a circular area 1" in apparent semidiameter. To derive the actual brightness or stellar magnitude,  $L$  must be modified by an empirical function of the phase angle;  $L$  is a measure only of the brightness which, if there were no dependence of apparent albedo on phase angle, would be determined by the area illuminated, and the relative intensity of the incident light per unit area which varies as  $1/r^2$ .

#### *Ephemerides for Physical Observations of Mars, Jupiter, and Saturn* (Pages 316–331)

These ephemerides give the time required for light to travel from the planet to the Earth, and the stellar magnitude and apparent diameter of the planet; and for the illuminated disk they give the position angle of the point of greatest defect of illumination, measured eastward from the north point of the disk, and the angular amount of the defect; the planetocentric angle  $i$  between the Sun and the Earth is also tabulated. In the ephemeris for Mars, the ratio  $k$  of the area of the illuminated apparent disk to the area of the entire apparent disk regarded as circular is included.

For Mars and Jupiter, quantities are given which determine the geocentric and heliocentric aspects of the planetographic coordinate systems on the surface of the planet, to which the markings on the disk are referred. The aspect

of the disk depends upon the positions of the Earth and the Sun relative to the different areas of the surface of the planet, or equivalently upon the apparent positions of the Earth and the Sun on the planetocentric celestial sphere at the different points of the surface. To represent these positions, coordinate systems are defined on the planetocentric sphere, by the plane of the equator of the planet and the plane of its orbit, in the same way as right-ascension and declination, and celestial longitude and latitude, are defined on the geocentric celestial sphere by the equator of the Earth and the ecliptic. Because of the mathematically indefinite radius of the celestial sphere, the same fundamental reference circles are defined on the geocentric sphere as on the planetocentric sphere by the orbital and equatorial planes of the Earth and the other planets.

On a planetocentric sphere, the apparent position of the Earth is diametrically opposite the geocentric position of the planet, and the Sun is opposite the heliocentric position. The planetocentric angular distance of the Earth from the equator of the planet, denoted by  $D_E$  and known as the planetocentric declination of the Earth, is numerically equal and opposite in sign to the geocentric angular distance of the planet from the plane of the equator of the planet. The angular distance in the plane of the planetary equator from the ascending node of the orbit of the planet on its equator eastward to the great circle through the Earth and the celestial pole of the planet, denoted by  $A_E$ , is known as the planetocentric right ascension of the Earth; it is equal to the geocentric longitude of the planet measured in the plane of its equator from the descending node of its orbit on its equator.

Similarly, the planetocentric right ascension of the Sun,  $A_S$ , is equal to the heliocentric longitude of the planet measured in the plane of its equator from the descending node of the orbit; and the planetocentric declination of the Sun,  $D_S$ , is numerically equal and opposite in sign to the heliocentric angular distance of the planet from the plane of the planetary equator. The planetocentric longitude of the Sun, denoted by  $L_S$  and measured in the plane of the orbit of the planet from the ascending node on its equator, is equal to the heliocentric orbital longitude of the planet reckoned from the descending node; it is tabulated only for Mars.

Planetographic longitudes on the surfaces of Mars and Jupiter are reckoned from  $0^\circ$  to  $360^\circ$  in the direction opposite the rotation, that is, eastward on the celestial sphere. The zero meridian from which the longitudes are measured is defined by the adopted position of the pole and an adopted value for the longitude of the meridian that passes through the central point of the disk at a selected epoch. The adopted longitude of the central meridian at the epoch and the rate of rotation of the planet determine the central meridian at any other time. The rotation is referred to the ascending node of the orbit on the equator of the planet, and the period is therefore known as the sidereal period of rotation; it differs slightly from the actual period of rotation, because of the precession of the axis of the planet.

For Mars, the position of the north pole that is used in computing the physical ephemeris was adopted in 1909, and the zero meridian is defined by

the tabular central meridian at Greenwich mean noon on 1909 January 15; but beginning with 1960, a period of rotation is adopted that differs from the value used before 1960. Consequently, from 1959 to 1960 there is a discontinuity in the tabular longitude of the central meridian, amounting to about  $-1^\circ$ . The adopted rotation elements of Mars are:

*North pole* (LOWELL and CROMMELIN, *Mon. Not. Roy. Astr. Soc.*, **66**, 56, 1905)

At the beginning of the year  $t$ ,

$$\alpha_0 = 21^h 11^m 10^s.42 + 1^s.565 (t - 1950.0),$$

$$\delta_0 = +54^\circ 39' 27'' + 12''.60 (t - 1950.0).$$

*Sidereal period of rotation* (ASHBROOK, *Astr. Jour.*, **58**, 145, 1953)

In Ephemeris Time,  $24^h 37^m 22^s.6689$ .

*Central meridian*, referred to the zero meridian of 1909

Longitude of central meridian,

$$1909 \text{ Jan. 15, G.M.N. (J.D. 241 8322.0), } 344^\circ.41.$$

Daily motion,  $350^\circ.891\ 962$ .

The tabular central meridian is for the geometric disk, not the illuminated disk; and the time of transit of the zero meridian is for the transit across the central point of the geometric disk.

The position angle of the axis is the angle which the meridian from the central point of the disk to the north pole of rotation forms with the declination circle through the central point, measured eastward from the north point of the disk.

For Jupiter, the adopted position of the pole is derived from the position for 1750 given by DAMOISEAU, *Tables Écliptiques des Satellites de Jupiter* (Paris, 1836), page i; the longitude of the central meridian that defines the zero meridian, and the rate of rotation, are adopted from the ephemeris last published by MARTH, *Mon. Not. Roy. Astr. Soc.*, **56**, 523, 1896:

*North Pole of Jupiter*

At the beginning of the year  $t$ ,

$$\alpha_0 = 17^h 52^m 00^s.84 + 0^s.247 (t - 1910.0),$$

$$\delta_0 = +64^\circ 33' 34''.6 - 0''.60 (t - 1910.0).$$

*Sidereal period of rotation*

*Central meridian*

Longitude,

$$1897 \text{ July 14, G. M. N. (J.D. 241 4120.0)} \quad 47^\circ.31 \quad 96^\circ.58$$

$$\text{Daily motion} \quad 877^\circ.90 \quad 870^\circ.27$$

System I applies to all points on or between the north component of the south equatorial belt and the south component of the north equatorial belt; System II applies north of the south component of the north equatorial belt, with some rare exceptions, and south of the north component of the south equatorial belt.

The tabular central meridians are for the geometric disk; applying to them the corrections in the column headed *Correction for Phase* gives the longitudes

of the central meridian of the apparent or illuminated disk. In addition, the longitude of the central meridian of the illuminated disk is tabulated at daily intervals in a separate ephemeris; the tables of the motion of the central meridian accompanying this ephemeris are based on the mean daily synodic rotations during the period when Jupiter is observable, which are  $877^{\circ}95$  for System I, and  $870^{\circ}30$  for System II. An accuracy of  $0^{\circ}.1$  for the central meridian of the illuminated disk is usually sufficient, and may readily be obtained from the daily ephemeris; interpolation in the 4-day ephemeris is less convenient, but may be made in the infrequent cases when an accuracy of  $0^{\circ}.01$  is needed.

The ephemeris for physical observations of Jupiter includes the period near conjunction, for the purpose of radio observations.

### Satellites

The ephemerides of the satellites are intended only for search and identification, not for the exact comparison of theory with observation; they are calculated only to an order of accuracy sufficient for the purpose of facilitating observations. They are corrected for light-time; the tabular values are directly comparable with observations at the tabular times. The value of the light-time used in calculating the ephemerides of the satellites is  $498^{\text{s}}.58$  for unit distance. The orbital elements and constants are given in the *Explanatory Supplement*.

The apparent orbit of a satellite is an ellipse on the celestial sphere, with semimajor axis  $a/\Delta$ , where  $a$  is the apparent semimajor axis at unit distance in seconds of arc and  $\Delta$  is the geocentric distance of the primary. The value of the eccentricity of the apparent orbit at opposition is used in calculating the tables for finding the position angle  $p$  of the satellite relative to the primary, measured from north toward east, and the apparent distance  $s$  from the central point of the disk of the primary. The effect of the eccentricity of the actual orbit upon its projection into the apparent orbit, and the variation of the eccentricity of the apparent orbit, are neglected. Approximately, therefore,  $s = F(a/\Delta)$ , where  $F$  is the ratio of  $s$  to the apparent distance at greatest elongation; and at the greatest elongations  $p = P \pm 90^{\circ}$ , where  $P$  is the position angle of the extremity of the minor axis of the apparent orbit that is directed toward the pole of the orbit from which the motion appears counterclockwise. With  $P_0$  denoting an arbitrary fixed integral number of degrees near the value of  $P$  at opposition, the value of  $p$  at any time is expressed in the form  $p_1 + p_2$ , where  $p_1$  is the sum of the approximate position angle  $P_0 + 90^{\circ}$  at elongation and the amount of motion in position angle since elongation, and  $p_2$  denotes the correction  $P - P_0$ . In the tables of  $p_1$  the tabular entry for argument  $0^{\text{h}} 00^{\text{m}}$  is the value of  $P_0 + 90^{\circ}$ .

The differences of right ascension and declination, in the sense "satellite minus primary", are approximately

$$\Delta\alpha = s \sin p \sec(\delta + \Delta\delta), \quad \Delta\delta = s \cos p,$$

in which  $s \sin p$  and  $s \cos p$  are the rectangular coordinates of the satellite in the directions perpendicular to the circle of declination and along this circle, respectively.

*Satellites of Mars* (Pages 332–335)

The ephemerides of the satellites of Mars are computed from the orbital elements given by H. STRUVE, *Sitzungsberichte der Königl. Preuss. Akademie der Wissenschaften*, 1911, page 1073.

*Satellites of Jupiter* (Pages 336–363)

The ephemerides of Satellites I–IV are based on SAMPSON's *Tables of the Four Great Satellites of Jupiter*, London, 1910; but they are computed in accordance with the procedures developed by H. ANDOYER, *Bulletin Astronomique*, 32, 177, 1915, in which a number of approximations and modifications of the tabular procedures are made.

The elongations of Satellite V are computed from circular orbital elements determined by A. J. J. VAN WOERKOM, *Astr. Pap. Amer. Eph.*, vol. XIII, Part I, 1950, pages 8, 14, 16.

The differential coordinates of Satellites VI and VII are computed from J. BOBONE's tables, *Astronomische Nachrichten*, 6279, 321, 1937, and 6309, 401, 1937.

The actual phenomena of Satellites I–IV are not instantaneous. Since the predicted times are for mid-phenomena, a satellite is usually observable after the given time of EcD and before the time of EcR. In the case of Satellite IV the difference is sometimes quite large. The light curves of the eclipse phenomena are discussed in *Planets and Satellites* (The Solar System, vol. III) ed. Gerard P. Kuiper and Barbara M. Middlehurst, 1961, pages 327–340.

The approximate configurations of Satellites I–IV are shown in graphical form, to facilitate identification, on pages facing the tabular ephemerides of the eclipses and other phenomena of the satellites. The central vertical band in each diagram represents the equatorial diameter of the disk of Jupiter; time is shown by the vertical scale, each horizontal line denoting 0<sup>h</sup> U.T., and the relative positions of the satellites at any time with respect to the disk of Jupiter are given by the curves. In constructing these diagrams, the coordinates of the satellites in the direction perpendicular to the equator of Jupiter are necessarily neglected.

For eclipses, the points *d* of immersion into the shadow and points *r* of emersion from the shadow are shown pictorially at the foot of the right-hand page for the superior conjunctions nearest the middle of each month; and at the foot of the left-hand page the rectangular coordinates of these points are given, in units of the equatorial radius of Jupiter. The axis of *x* is parallel to the equator of Jupiter, positive toward the east, and the axis of *y* is positive toward the north pole of Jupiter. The suffix 1 refers to the beginning of an eclipse, the suffix 2 to the end of an eclipse.

*Satellites and Rings of Saturn* (Pages 364–379)

The ephemeris of the rings of Saturn is computed from the elements of the plane of the rings determined by G. STRUVE, *Veröff. d. Universitätssternwarte zu Berlin-Babelsberg*, VI, 4, page 49, 1930. The apparent outer dimensions of the outer ring are according to H. STRUVE, *Pub. de l'Obs. Central Nicolas*, XI, page

226, 1898; the factors for computing the relative dimensions of the rings are from BESSEL, *Abhandlungen*, I, pages 110, 150, 319, except those for the dusky ring which are based on the observations of various astronomers.

The ephemeris of the rings gives the quantities that determine the Saturnicentric positions of the Earth and the Sun referred to the plane of the rings, upon which the appearance of the rings depends; the tabular quantities are:

$U$ , the geocentric longitude of Saturn, measured in the plane of the rings eastward from its ascending node on the mean equator of the Earth; the Saturnicentric longitude of the Earth, measured in the same way, is  $U+180^\circ$ .

$B$ , the Saturnicentric latitude of the Earth referred to the plane of the rings, positive toward the north; when  $B$  is positive, the visible surface of the rings is the northern surface.

$P$ , the geocentric position angle of the northern semiminor axis of the apparent ellipse of the rings, measured from north toward east.

$U'$ , the heliocentric longitude of Saturn, measured in the plane of the rings eastward from its ascending node on the ecliptic; the Saturnicentric longitude of the Sun, measured in the same way, is  $U'+180^\circ$ .

$B'$ , the Saturnicentric latitude of the Sun referred to the plane of the rings, positive toward the north; when  $B'$  is positive, the northern surface of the rings is the illuminated surface.

$P'$ , the heliocentric position angle of the northern semiminor axis of the rings on the heliocentric celestial sphere, measured eastward from the circle of latitude through Saturn.

The ephemeris of the rings is corrected for light-time.

The ephemerides of the six inner satellites and of Iapetus are computed from the orbital elements determined by G. STRUVE, *Veröff. d. Universitätssternwarte zu Berlin-Babelsberg*, VI, Parts 4 (1930) and 5 (1933). The ephemeris of Hyperion is computed from the elements given by J. WOLTJER, Jr., *Annalen van de Sterrewacht te Leiden*, XVI, Part 3, page 64, 1928; and of Phoebe, from the theory by F. E. ROSS, *Annals of Harvard College Observatory*, LIII, Number VI, 1905.

For the eight inner satellites, the times of conjunctions and elongations, and tables for finding the approximate apparent distance  $s$  and position angle  $p$ , are given. On the diagram of the orbits of Satellites I–VII, the points of eastern elongation are marked as “0”; and from the tabular times of these elongations, the apparent position of a satellite at any other time may be marked on the diagram by setting off on the orbit the elapsed interval since last eastern elongation. For Hyperion and Iapetus, ephemerides of the differential coordinates are also included; and an ephemeris of differential coordinates is given for Phoebe.

In calculating the elongations and conjunctions, and the tables of apparent distance and position angle, solar perturbations are not included for any of the

eight satellites; and for the five innermost satellites, the orbital eccentricity  $e$  is neglected. However, the mean longitude  $L$  and mean anomaly  $M$ , calculated from accurate values of the orbital elements, and including for Titan the solar perturbations, are tabulated at 10-day intervals for the eight inner satellites, and with them are given the values of the elements that have large variations. From the orbital position of the satellite determined with these tabular values, and the Saturnicentric position of the Earth referred to the orbital plane of the satellite, values for the apparent distance and position angle may be calculated, and differential coordinates in right ascension and declination determined.

The mean orbital longitude  $L$  and the true longitude  $u$  of the eight inner satellites, and the longitude  $\theta$  of the ascending node of the orbit on the plane of the rings, are measured from the ascending node of the ring-plane on the mean equator of the Earth;  $L$  and  $u$  are reckoned along the ring-plane to the node of the orbit, then along the orbit. Prior to 1966,  $L$  and  $u$  for Hyperion and Iapetus were reckoned from the node of the orbit on the equator of the Earth, and ephemerides were given for  $U$ ,  $B$ , and  $P$  referred to the orbital plane. The tabular values of  $L$  and  $M$  are the geometric values at the tabular times, not corrected for light-time.

The formulae and constants for obtaining the true orbital longitude  $u$  and the radius vector  $r$  of the eight inner satellites are:

*Mimas*

$$\begin{aligned} u &= L + 2^{\circ}303 \sin M + 0^{\circ}029 \sin 2M, \\ \frac{r}{a} &= 1.0002 - 0.0201 \cos M - 0.0002 \cos 2M, \\ a &= 255''.9, \quad \sin \gamma = 0.0265. \end{aligned}$$

*Enceladus*

$$\begin{aligned} u &= L + 0^{\circ}509 \sin M, \\ \frac{r}{a} &= 1 - 0.0044 \cos M, \\ u - \theta &= 36^{\circ} + 263^{\circ}15 \text{ (J.D.} - 243\,6000.5), \\ a &= 328''.3, \quad \sin \gamma = 0.0004. \end{aligned}$$

*Tethys*

$$\begin{aligned} u &= L, \quad \frac{r}{a} = 1, \\ a &= 406''.4, \quad \sin \gamma = 0.0191. \end{aligned}$$

*Satellites of Uranus* (Pages 380–382)

The ephemerides of Ariel and Umbriel are computed from the orbital elements determined by NEWCOMB, *Washington Obs. for 1873*, App. I; of Titania and Oberon, from the elements by H. STRUVE, *Abh. d. K. Preuss. Akad. d. Wiss.*, 1912. STRUVE's elements of the plane of the orbits are adopted for all four satellites.

*Satellites of Neptune* (Page 383)

The ephemeris of Triton is calculated from elements by W. S. EICHELBERGER and ARTHUR NEWTON, *Astr. Pap. Amer. Eph.*, vol. IX, Part III, 1926.

**Sunrise, Sunset, and Twilight** (Pages 384–391)

The tabular times of sunrise and sunset are the instants when the true geocentric zenith distance of the central point of the disk is  $90^{\circ} 50'$ . With an adopted value of  $34'$  for the horizontal refraction, and  $16'$  for the semidiameter, the apparent zenith distance of the upper limb, neglecting parallax, is then  $90^{\circ}$ , and the limb is apparently on the astronomical horizon. The tabular times of the beginning and end of astronomical twilight are the instants when the true geocentric zenith distance of the central point of the disk is  $108^{\circ}$ .

The tabular values give the local mean times of the phenomena on the meridian of Greenwich for northern latitudes up to  $+60^{\circ}$ . No interpolation is usually made for the local times at other longitudes; the error from neglecting the variation with longitude is negligible, amounting to a maximum of  $2^m$  in latitude  $60^{\circ}$  north. To obtain the local *standard* time or zone time, increase the local time four minutes for each degree of longitude west of the standard meridian, or decrease the local time four minutes for each degree east of the standard meridian.

In a *southern* latitude, the time of sunrise, sunset, or beginning or end of twilight, is obtained for any date by entering the table with the same *numerical value* of the latitude, but for a date about six months earlier or later than the actual date, and applying a small correction to the tabular time; these dates and corrections are tabulated at the foot of the page. The periods during which twilight lasts all night in southern latitudes may be found by substituting for the northern latitudes the corresponding southern latitudes, and for the dates the corresponding dates taken from the foot of the page.

Example

On 1967 May 5, in latitude  $-38^{\circ}$ , required the times of sunrise, sunset, and beginning and end of twilight. November 7 is the corresponding date, northern latitude, and the correction is  $+13^m$ .

|   | Beginning<br>of<br>Twilight |    | Sunrise |    | Sunset |    | End of<br>Twilight |    |
|---|-----------------------------|----|---------|----|--------|----|--------------------|----|
|   | h                           | m  | h       | m  | h      | m  | h                  | m  |
| Lat. $+38^{\circ}$ , Nov. 7 . . . . .           | 5                           | 01 | 6       | 31 | 16     | 56 | 18                 | 25 |
| Auxiliary table . . . . .                       | +13                         |    | +13     |    | +13    |    | +13                |    |
| <hr/>   |                             |    |         |    |        |    |                    |    |
| Lat. $-38^{\circ}$ , Local mean time, May 5 . . | 5                           | 14 | 6       | 44 | 17     | 09 | 18                 | 38 |

The tabular values are based on the “Tables of Sunrise, Sunset, and Twilight” published as a *Supplement to the American Ephemeris for 1946*. These

tables provide for obtaining the times at any point on the Earth in any year of the twentieth century.

### Moonrise and Moonset (Pages 392-423)

The tabular times of moonrise and moonset are the instants when the true geocentric zenith distance of the central point of the disk is  $90^\circ 34' + s - \pi$ , where  $s$  is the semidiameter and  $\pi$  the horizontal parallax of the Moon, and  $34'$  is the adopted horizontal refraction; the upper limb is then apparently on the astronomical horizon. No allowance is made for the phase of the Moon.

The tabular times are for the meridian of Greenwich, and are given both for northern and for southern latitudes from  $+60^\circ$  to  $-60^\circ$ . To obtain the local mean time of moonrise or moonset at other longitudes that are 12 hours or less west from Greenwich, take out the tabular times for the given date and for the next following date; at longitudes 12 hours or less east from Greenwich, take out the times for the given date and for the date preceding. Subtract the time on the earlier date from the time on the later date; multiply the difference by the twenty-fourth part of the longitude in hours and decimals of an hour, positive if west, negative if east; apply the product as a correction to the tabular time on the given date to obtain the required local mean time. To obtain the standard time or zone time, increase the local time by four minutes for each degree of longitude west of the standard meridian, or decrease the local time by four minutes for each degree east of the standard meridian.

### Examples

1. For 1967 January 21, find the standard time of moonrise and moonset at longitude  $145^\circ$  or  $9^h 40^m$  east from Greenwich ( $20^m$  west of the standard meridian) and latitude  $27^\circ 50'$  south.

**Astronomical Observatories** (Pages 424-444)

The list of optical observatories is followed by a list of radio observatories; and an *Index List* is given for finding observatories that are better known by special names than by their geographic location.

The latitudes in most cases are astronomical; but in some instances they have been determined by geodetic triangulation from other points. The geocentric coordinates  $\rho \sin \phi'$  and  $\rho \cos \phi'$  are calculated for the International Ellipsoid; the altitude is included in every case where it is known.

The last two columns on the right-hand pages contain the parallax constants

$$\begin{aligned}\Delta_{\alpha} &= -\rho \cos \phi' \sin 8''.80 \\ &= -426.64 \rho \cos \phi' \times 10^{-7}, \\ \Delta Z &= -\rho \sin \phi' \sin 8''.80 \\ &= -426.64 \rho \sin \phi' \times 10^{-7};\end{aligned}$$

the tabular values are in units of the seventh decimal. Formulae for parallax corrections in right ascension and declination, and for corrections to the equatorial rectangular coordinates of the Sun to eliminate parallax, are given at the foot of each right-hand page.

**Tables** (Pages 445-473)

A list of the individual tables is given in the *Contents*.

Table I of Julian Day Numbers is explained in the section on the calendar.

Table II, for determining latitude and azimuth from observations of Polaris, includes the precepts for the use of the table at the foot of each page.

Table III, for the reduction of mean places from one epoch to another, is explained in the section on mean places of stars. Tables IV-VI relating to reductions for precession, nutation, and differential aberration, include precepts for their use, and are referred to in the section on Day Numbers.

The precepts for using Table VII to calculate geocentric coordinates are given below the table.

Tables VIII-XII for conversions of measures of time, and the Interpolation Tables XIII-XVII are self-explanatory.

# INDEX
